For example, in the African language Ewe, high tones are realized as rising after noun-initial voiced obstruents: /vǐ/ > [vǐ] 'child'. To express such facts, Halle and Stevens (2002), drawing on their own earlier research as well as work summarized in Bao (1999), propose a feature-geometrical account in which consonants and tones share the features in the third column in Table 4. In this model, the feature [+slack vocal cords] is interpreted phonetically as voicing in obstruents and low tone in vowels, while [+stiff vocal cords] is interpreted as voicelessness in obstruents and high tone in vowels. Halle and Stevens propose that both of these features link directly to the Glottal tier (analogous to the Laryngeal tier in Figure 1), in conformity with (1e).

However, many linguists have noted that not all tone languages exhibit the relations in Table 4. Not only are these relations sometimes broken by historical change, but many, perhaps most, tone languages do not exhibit any phonological consonant/tone interactions at all. For example, in many tone languages, such as Mende or Kikuyu (Gikuyu), high tones spread freely across all obstruents, both voiceless and voiced. It appears that in order to render the Halle/Stevens model compatible with such facts, a feature-geometric model must be enriched in one of at least two ways. One solution would allow tonal geometry to be parameterized across languages, requiring a relaxation of (1c). In this approach, tone features would dock to the Glottal node in languages that, like Ewe, exhibit the consonant/tone interactions in Table 4, while in languages lacking such interactions, such as Mende and Kikuyu, tone features would dock to a higher-level node, such as the Syllable or Mora. Another solution would maintain a universal tonal geometry but would allow tone features in consonants to dock to a different node from tone features in vowels. In this approach, Ewe, Mende, and Kikuyu would all have the same representations, and what would differ would be the level of structure accessed by the tone rules. This solution, like the Clements/Hume proposal for place features, would require a weakening of principle (1e). At the present time both of these approaches, and variants of them, are undergoing active research (for related discussion and further references, see Yip, 2002: 56–61).

One more recent proposal may be noted. In early work on feature geometry, Hayes (1986) suggested that feature classes are built up derivationally, introduced only when they are triggered by rules. Developing this suggestion within a constraint-based framework, Clements (2001) proposes that though the feature hierarchy is universal (cf. [1c]), not all languages make use of all structure. Rather, structure is present just to the extent that it is activated in a particular language. For example, French, with no place assimilation, does not activate the Place node. In the limit case, a language with no phonology whatsoever – that is, one in which underlying and surface representations are identical – would have no tier structure at all. Clements shows that this approach can provide a solution to several traditional problems involving long-distance harmony and assimilation.

Phonetic Extensions of Feature Geometry

Feature geometry drew much attention in the late 1980s and 1990s, leading to the development of many further proposals within the general framework of autosegmental phonology. Related models have been developed in other nonlinear phonological frameworks, such as dependency phonology (e.g., Smith, 1989; van der Hulst, 1989) and government phonology (e.g., Harris, 1994; Scheer, 1998). Given limits of space, we discuss just one other important development here, involving the extension of feature-geometrical approaches to phonetics. This development aims to achieve a full integration, as opposed to *ad hoc* 'interface,' of phonetics and phonology. Three proposals are reviewed here.

First, from the point of view of precedence and influence, the framework of articulatory phonology as developed by Browman and Goldstein (1989, 1992, etc.) deserves special attention. The hypothesis underlying this framework is that the basic principles underlying spoken language are best understood when viewed as patterns of coordinated articulatory gestures. Articulatory phonology proposes to model phonetic and phonological patterns in terms of 'articulatory scores,' that is, formal representations consisting of abstract gestures and their patterns of coordination. Given that feature-geometrical representations have already brought to light structures that resemble abstract 'maps' of the vocal tract, it is not surprising to find that there is a close resemblance between gestural scores and feature-geometrical representations. Gestures are defined in terms of articulator sets whose content is similar to that of the Oral Cavity node in some feature geometry models (Clements and Hume, 1995) or to the Place node in others (Padgett, 1995). Each articulator set includes specifications for constriction degree, constriction location, constriction shape, and stiffness for a particular articulator (Lips, Tongue Tip, Tongue Body, etc.). These components closely parallel the features of feature geometry, as shown in Table 5.

Nevertheless, articulatory phonology differs from feature geometry in several important respects. First, gestures have temporal duration, while features

Table 5 Gestural components compared to features

Articulatory phonology	*Feature geometry*
LIPS	[labial]
Tongue Tip (TT)	[coronal]
Tongue body (TB)	[dorsal]
Closed	[−continuant]
Critical	[+continuant] in [−sonorant]
Dental	[+distributed]
etc.	

do not. Second, while features are categorical (typically one valued or at most two valued), the components of gestures are quantitatively specified. Third, while features are defined in terms of quantal articulatory-acoustic relationships (Stevens, 1989), gestures are defined in terms of an articulatory task-dynamic model (Salzman and Kelso, 1987). Again, while most features are represented on separate tiers in feature-geometrical representations, the components of gestures (constriction location, constriction degree, etc.) are bundled together with an articulator on the same 'tier' of the gestural score. Still another difference is that while feature geometry places class nodes directly in the feature representation, articulatory phonology locates them outside the articulatory score.

All these differences make precise predictions that help to distinguish the relative sphere of application of each theory. It does not appear at present that either theory fully covers the empirical domain of the other; thus, feature geometry is too coarse grained to capture a great many articulatory regularities at the phonetic level, as Browman and Goldstein have amply shown, while articulatory phonology is too fine grained to capture important generalizations at the phonological level, such as feature economy (Clements, 2003). It may be that in spite of their close resemblance, the two theories must still be viewed as interfaced, rather than truly fused (Zsiga, 1997). Nevertheless, articulatory phonology has taken a major step toward bringing phonology and phonetics closer together.

Two other approaches have attempted to achieve similar goals. Keyser and Stevens (1994) propose a theory of feature geometry based largely on phonetic criteria. Drawing almost exclusively on articulatory and acoustic considerations, they attempt to bring the phonological tree into closer agreement with known facts about the control of articulatory processes and their corresponding acoustic correlates. In another direction of research, Clements and Hertz (1996) propose an integrated representational system (IRS) for expressing phonology-acoustic relations, providing a formal theory of acoustic scores comparable to the articulatory scores of Browman and Goldstein. Their approach, like that of Browman and Goldstein, must be considered an interface model, in the sense that phonological structure and acoustic scores constitute separate but related planes within a complex representational space.

Current Trends and Perspectives

This article reviews a number of proposals to explain the behavior of speech sounds in terms of models of segment-internal feature structure. These proposals have been developed within the broader framework of nonlinear phonology. An underlying assumption has been that well-elaborated models of representation can go a long way toward constraining phonological structure, allowing the expressive power of rules to be severely limited. As McCarthy has put it (1988: 84), "[I]f representations are right, the rules will follow."

Two newer developments in the past decade have placed research on feature organization in a new light. The first is optimality theory, with its emphasis on ranked constraints, as opposed to rules and representations. Linguists working within this framework have taken a new look at many classic problems that were earlier dealt with in representational terms, such as vowel and consonant harmony, and have proposed new explanations in which constraints rather than multitiered representations play a leading role. The second is the increasing reconciliation of phonetics and phonology, already mentioned, in which the explanation of cross-linguistic trends in phonological patterning is sought more often in constraints on articulation, audition, and perception than in linguistic formalisms.

In formulating strict, testable predictions about a wide range of phonological processes, feature geometry and related approaches have provided a powerful engine for research and have brought to light a great many discoveries that would hardly have been conceivable in their absence. They continue to raise substantive questions concerning segmental interactions, several of which, as noted in this article, remain essentially unsolved at the present time. Multitiered feature representations are compatible in principle with constraint-based approaches (e.g., Zoll, 1998) and can be defined in terms of constraints on feature configurations (e.g., Uffmann, 2005). Perhaps most importantly, by invoking the abstract, higher-level cognitive organization of speech, feature representations provide a necessary counterpart to phonetically driven approaches, offering explanation in areas where phonetics does not reach (Clements, in press).

The study of feature organization can be expected to continue to play a central role in future work, though perhaps in a somewhat different form.

Ferguson, Charles A. (1921–1998)

J Fishman, Bronx, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

One of America's leading linguists, with an unusually broad range of well-developed interests and a highly significant number of organizational accomplishments, Charles A. Ferguson was born on July 6, 1921, in the Germantown section of Philadelphia, Pennsylvania, the city in which he also grew up and received his elementary, secondary, and higher education: University of Pennsylvania, A.B., 1942 (Philosophy); A.M., 1943; and Ph.D., 1945 (Oriental Studies). Having specialized in Arabic (his M.A. thesis was on the Moroccan Arabic verb) and Bengali (his doctoral dissertation was on standard colloquial Bengali), Ferguson was initially employed as a linguist for Near Eastern languages by the Foreign Service Institute of the U.S. Department of State, from 1946 to 1955. During this time, he established the Foreign Service Institute and Language School, attached to the American Embassy in Beirut. Thereafter, he taught briefly at the Institute of Languages and Linguistics at Georgetown University and Deccan College in India; he then joined the Center for Middle Eastern Studies at Harvard University as a lecturer in linguistics and in Arabic, remaining there until 1959. In 1959, Ferguson became the founding director of the Center for Applied Linguistics in Washington, D.C., a position that he maintained until 1966. Under Ferguson's leadership, the center developed from initially being under the auspices of the Modern Language Association of America into an independent institution with a staff of approximately 100 and recognized international stature in most areas of applied linguistics. In time, the field of applied linguistics became firmly placed on the agenda of linguistics throughout the world, its high stature to this very day deriving from the combined efforts and expertise of both Ferguson and the center. He also led the center in its focus upon language teaching, literacy, and language planning, interests that he actively pursued for the rest of his life.

While directing the center, Ferguson also served as a member of the Committee on Linguistics and Psychology of the Social Science Research Council (1959–1961) and later became a founding member and chair of the council's Committee on Sociolinguistics (1964–1970). Over the course of half a dozen years, Ferguson's leadership enabled the latter committee to establish this new area of specialization as a recognized field of linguistic research and instruction, both in the United States and throughout much of the world, with a wide array of courses, journals, conferences, and research projects quickly being devoted to it. Ferguson's continued identification with sociolinguistics is evidenced by the very large number of articles and books that he authored, coauthored, edited, and coedited in this field. In addition to sociolinguistics ('language use in society') Ferguson also made pioneering contributions to the study of language universals, first- and second-language development, and language change.

In 1967, Ferguson became Professor of Linguistics and the founding chairperson of the Committee on (later: Department of) Linguistics at Stanford University (California). From the very outset after Ferguson's arrival, linguistics at Stanford was characterized by a strong interest in many of Ferguson's areas of specialization, including not only those already mentioned in this article but also child language, language and religion (particularly non-Western religions and also the study of saints' lives), and, of course, all of the standard areas of general linguistics.

Among Ferguson's seminal sociolinguistic publications was his relatively brief paper 'Diglossia' (1959), which dealt with languages and language varieties in long-term, widely accepted, and functionally complementary operation within the same speech community (classical and vernacular Arabic, High German and Swiss German, Katharevousa and demotic Greek, Classical and vernacular Tamil, Haitian Creole and French, etc.). This article stimulated literally hundreds of conference papers, symposia, and journal articles and many books and, indeed, continues to do so to this very day (e.g., Hudson and Fishman, 2002; Belnap and Fishman, 2003) among a very diverse group of colleagues, students, and researchers internationally and in such distinct fields as sociolinguistics, language planning, bidialectalism, and bilingualism.

Ferguson, a person of great faith, modesty, and patience, was often honored by the language studies professions, among these honors being the publication of a collection of his selected papers (Dil, 1971) as well as a two-volume Festschrift in honor of his 65th birthday (Fishman *et al.*, 1986a, 1986b). The latter contains a full bibliography of his published works (books, articles, and reviews) until 1985 that is supplemented in Huebner (1986).

Upon his retirement from Stanford (1986), Ferguson became Professor Emeritus but continued to live near Stanford University (in Palo Alto, California) and to work in many of the areas of interest that he had pioneered and fostered throughout his exceptionally

productive and stimulating career. During this period, he completed a new collection of his sociolinguistic papers (Huebner [ed.], 1996), as well as a collection of his papers related to Arabic (1996). Several memorial volumes in his honor have also appeared (e.g., Hudson, 1996; Belnap and Fishman, 2003).

Fick, August Konrad Friedrich (1833–1916)

R Schmitt, Laboe, Germany

© 2006 Elsevier Ltd. All rights reserved.

August Fick, born on May 5, 1833, in Petershagen (near Minden), Germany, did philological studies in Göttingen (comparative grammar [with Theodor Benfey] and classical and Oriental languages) and then taught there for many years at a grammar school. In 1876, when his most important books had been published, he was appointed to a newly founded extraordinary professorship of Indo-European studies at the University of Göttingen. In 1888, he moved to Breslau, where he had been offered the chair of comparative linguistics. For reasons of health, he became professor emeritus in 1891, but by living mostly in places with a healthy climate, he was able to continue working until he died on March 24, 1916, in Hildesheim.

Like August Friedrich Pott, Fick, owing to his strength of imagination and his power of reasoning, discovered great quantities of plausible etymologies in the field of the Indo-European languages. He became the first to compile a comparative dictionary of the Indo-European languages (1868), thereby reconstructing the lexical stock of the proto-language. In a second stage, he tried to refine this work and to combine it with August Schleicher's family-tree theory by drawing up the lexical stock of several prehistoric subgroups. In any case, those investigations shedding light on the prehistory of the individual Indo-European languages, particularly those of Old Europe (1873), had a strong effect on the consolidation of Indo-European comparative linguistics.

However, most of Fick's publications dealt with questions of the Greek language and specifically with Greek anthroponyms. One of his great achievements was describing, for the first time, the entire system of Indo-European personal names and the structure underlying it. In 1874, he proposed that the compound two-stem names, as well as the shortened names based on them (and including the hypocoristics), were formed in the same manner among most of the Indo-European peoples.

In later years, he turned to studies on the pre-Greek geographical names (1905) and uncovered a prehistoric layer of toponyms common to ancient Greece and Asia Minor. However, those works seem to lack the strong methodological principles followed elsewhere, as well as a sufficient backup in the material discussed, so experts have regarded them with suspicion. The same applies to Fick's work on the Homeric epics and Hesiod's poems. Convinced that they had not been originally written in the Ionic dialect, he attempted to reconstruct their initial Aeolic text in an entirely one-sided manner of reasoning and without regard to the particular character of the early Greek poetic language and to the history and prehistory of the Homeric epic poems in general.

Fictional Discourse: Philosophical Aspects

D Davies, McGill University, Montreal, Canada

© 2006 Elsevier Ltd. All rights reserved.

Fictional discourse is among the most superficially unproblematic yet philosophically puzzling of linguistic phenomena. We usually have little difficulty distinguishing fictional from nonfictional writings. We easily make sense of what is set out within the pages of fictions, and readily agree that Pegasus is a winged horse and not a one-legged donkey. Nor are we unreflectively perplexed by the feelings aroused in us by fictions. But each of these issues – the nature of fictional discourse, its meaningfulness, our ability to determine what is true in a fiction, and our capacity to be moved by it – has engendered heated philosophical debate that shows no sign of abating. While some of these issues concern only philosophers of art and literature, others bear on wider issues in ontology and the philosophy of language.

The Nature of Fictional Discourse

As will become apparent, a number of significantly different linguistic phenomena might be classified as forms of fictional discourse, but the core phenomenon is the use of language in fictional narratives such as the Sherlock Holmes stories. The fictionality of such narratives cannot be simply a matter of whether they portray actual happenings and actual agents, for works of fiction seem to contain numerous truths about the real world – e.g., true statements about the geography of Victorian London in Dickens's *Bleak house*. Furthermore, some paradigmatic works of nonfiction, such as medieval texts on alchemy, are largely false. Nor can the style of narration or the use of 'literary' techniques serve as a criterion of fictionality; there are non-fictional works that make free use of the narrative structures and stylistic devices typical of fiction (e.g. Mailer's *The executioner's song*), and celebrated works of fiction that adopt the style of nonfictional genres of writing (e.g. the 'academic' style of Nabokov's *Pale fire*).

The fictionality of a narrative may therefore depend upon **how it functions**, or **how it was designed to function** – either the function conferred upon it by its users (e.g., Walton, 1990), or its author's intention that it function, or be used, in a certain way. Philosophers attracted by the latter analysis have drawn upon the more general notion of a speech act, that is, an action performed by using language (verbal or nonverbal) in a certain way (Searle, 1975). The paradigm speech act is assertion, and Searle has maintained that fiction results when an agent **pretends** to assert what is stated by the sentences that make up a narrative. Given that there seem to be pretended assertions that do not result in fictions – e.g. a satirist's mimicking of a politician, Currie (1990) proposed that fiction results from the genuine performance of a speech act, but one that differs from assertion in that, whereas the latter requires that the speaker intend her audience to **believe** what she states, the author of a fictive utterance intends that her audience **make believe** what is narrated (see also Lamarque, 1996). To understand a work of fiction, then, is to grasp what it is that, as reader, one is intended to make believe.

Truth in a Fiction

If this is on the right track, what reading strategies should one adopt to determine what one **is** required to make believe to count as understanding what is

Fictional Discourse: Philosophical Aspects

D Davies, McGill University, Montreal, Canada

© 2006 Elsevier Ltd. All rights reserved.

Fictional discourse is among the most superficially unproblematic yet philosophically puzzling of linguistic phenomena. We usually have little difficulty distinguishing fictional from nonfictional writings. We easily make sense of what is set out within the pages of fictions, and readily agree that Pegasus is a winged horse and not a one-legged donkey. Nor are we unreflectively perplexed by the feelings aroused in us by fictions. But each of these issues – the nature of fictional discourse, its meaningfulness, our ability to determine what is true in a fiction, and our capacity to be moved by it – has engendered heated philosophical debate that shows no sign of abating. While some of these issues concern only philosophers of art and literature, others bear on wider issues in ontology and the philosophy of language.

The Nature of Fictional Discourse

As will become apparent, a number of significantly different linguistic phenomena might be classified as forms of fictional discourse, but the core phenomenon is the use of language in fictional narratives such as the Sherlock Holmes stories. The fictionality of such narratives cannot be simply a matter of whether they portray actual happenings and actual agents, for works of fiction seem to contain numerous truths about the real world – e.g., true statements about the geography of Victorian London in Dickens's *Bleak house*. Furthermore, some paradigmatic works of nonfiction, such as medieval texts on alchemy, are largely false. Nor can the style of narration or the use of 'literary' techniques serve as a criterion of fictionality; there are non-fictional works that make free use of the narrative structures and stylistic devices typical of fiction (e.g. Mailer's *The executioner's song*), and celebrated works of fiction that adopt the style of nonfictional genres of writing (e.g. the 'academic' style of Nabokov's *Pale fire*).

The fictionality of a narrative may therefore depend upon **how it functions**, or **how it was designed to function** – either the function conferred upon it by its users (e.g., Walton, 1990), or its author's intention that it function, or be used, in a certain way. Philosophers attracted by the latter analysis have drawn upon the more general notion of a speech act, that is, an action performed by using language (verbal or nonverbal) in a certain way (Searle, 1975). The paradigm speech act is assertion, and Searle has maintained that fiction results when an agent **pretends** to assert what is stated by the sentences that make up a narrative. Given that there seem to be pretended assertions that do not result in fictions – e.g. a satirist's mimicking of a politician, Currie (1990) proposed that fiction results from the genuine performance of a speech act, but one that differs from assertion in that, whereas the latter requires that the speaker intend her audience to **believe** what she states, the author of a fictive utterance intends that her audience **make believe** what is narrated (see also Lamarque, 1996). To understand a work of fiction, then, is to grasp what it is that, as reader, one is intended to make believe.

Truth in a Fiction

If this is on the right track, what reading strategies should one adopt to determine what one **is** required to make believe to count as understanding what is

'true in a story'? Not everything explicitly affirmed by the narrator of a story can be true in the story, for there are deceived, or deceiving, or ironic narrators. Nor should we restrict what is true in a story to what is explicitly affirmed by a trusted narrator, for sometimes, as in ordinary discourse, we take a narrator to be communicating more by her words than is strictly stated. We also assume, in our reading, that many things are true in a story although they are neither explicit nor implicit in the trustworthy affirmations of the narrator. We must therefore explain how we determine the unspecified background of general propositions that are nonexplicitly true in a given story. One strategy, here, appeals to what philosophers term "possible worlds" – roughly speaking, alternative ways the actual world might have been (Lewis, 1983): what is true in a (fictional) story N is decided by reference to possible worlds in which those things that are explicitly or implicitly true in the text of N are actually true. The task, then, is to pick out a particular group of such possible worlds as the ones that determine what else is true in the story.

A general problem for any such account of fictional truth, however, is that it cannot deal with stories in which **inconsistent** truths obtain – for example, certain sorts of time-travel stories – since possible worlds must themselves be **consistent** in order to be possible. To resolve this problem, Currie has proposed an analysis not in terms of possible worlds in which a given set of beliefs is true, but, rather, in terms of belief-sets themselves. He maintained that, in reading fictional narratives, we make believe that we are being informed about the events in the story by a reliable source, the so-called fictional author of the story. It is by reference to the beliefs attributable to the fictional author (the f.a.) – a completely reliable source of information about the narrated events – that the reader determines what is true in the story. The reader is supposedly guided here by the text itself, which provides evidence as to the f.a.'s character and psychological idiosyncracies, and by background assumptions – based on knowledge of the real author – as to the historical situatedness of the f.a. But it is open to question whether these resources are adequate to the task (see Davies, 1996).

Semantics of Fictional Discourse

The suggested strategies are supposed to explain how, given an instance of fictional discourse, we can understand what is true in the narrative presented through that discourse. Even if the author does not assert the sentences in such a discourse, it is assumed that the sentences themselves provide us with the content for our acts of make-believe. The use of language in fictional discourse is thus assumed to differ pragmatically rather than semantically from its use in nonfictional discourse (Gale, 1971). This is unproblematic when fictional discourse predicates nonactual properties of actual things – when, for example, Chancery is represented by Dickens as being shrouded in an impenetrable fog. But problems arise when a sentence S in fictional discourse contains what appears to be a proper name N (e.g. 'John Jarndyce,' as it occurs in *Bleak house*), which is not plausibly taken as denoting an actual person, place, or event. Suppose 'fictional names,' as Currie terms them, are genuine proper names, and that the same semantic principles apply to fictive and nonfictive discourse. Then, given the widely accepted 'direct reference' theory of proper names (Kripke, 1972), where a proper name contributes to the meaning of a sentence only the individual it denotes, S is meaningful only if N is a genuinely denoting term. If, by definition, no actual person, place, or event exists that is denoted by a fictional name – if such names are empty – how can we explain our seeming ability to understand sentences containing fictional names, and to hold some of them expressive of what is 'true in the story'?

Something, it seems, has to give. That is:

a. fictional names do genuinely denote, or
b. S's logical form is not as it appears to be, and fictional names do not function as proper names, or
c. our ability to make sense of S is compatible with S's being meaningless.

Option (a) is most famously associated with Meinong (1960), who held that there are nonexistent objects corresponding to unactualised sets of properties. Contemporary Meinongians, such as Parsons (1980) and Zalta (1983), have asserted that fictional characters are nonexistent objects of this kind, and that fictional names denote fictional characters so construed. An alternative strategy is to take fictional names to denote nonactual but possible objects that exist in other possible worlds (Plantinga, 1974; Lewis, 1983). Less ontologically profligate is the contention that fictional characters exist as 'abstract artifacts' (Thomasson, 1999) or as theoretical entities required to make sense of our critical practice (Van Inwagen, 1977), where such entities depend for their being on the activities of authors or critics. Those who choose option (a) must explain how fictional names are able to refer to fictional objects, as abstract entities, if names secure their reference through some kind of causal/historical link with their denotata, and how fictional characters are individuated. Arguably, Meinongians are able neither to meet these challenges nor to validate our intuition that authors create

the characters in their works (Thomasson, 1999), whereas, so it is claimed, these difficulties can be surmounted if fictional characters are taken to be abstract artifacts.

Option (b) requires that sentences containing fictional names be paraphrased such that they no longer contain such denoting expressions but are meaningful and possess appropriate truth values. Russell (1990), for example, analyzed sentences such as 'Pegasus flies' as quantified sentences affirming the existence of something that is a winged horse and flies: fictional names, like all standard names for Russell, are disguised definite descriptions. But this strategy makes sentences containing fictional names come out false unless by chance there is an existent fitting the relevant description. One response, here, is to take sentences occurring in fictional discourse to have a suppressed 'in the story' operator, while retaining the idea that fictional names, in such contexts, are disguised descriptions (Currie, 1990).

Option (c) grants that fictional names are genuine names and that they are empty, and therefore that sentences containing fictional names are meaningless. We are, however, able to understand fictions and determine what is true in a story, since, in engaging with a fiction, we make believe that the contained sentences are meaningful and that they have the relevant truth values (Walton, 1990).

A problem that is especially acute for those who choose option (b) is accounting for occurrences of fictional names in other kinds of linguistic contexts where it is difficult to deny our commitment to the reality of fictional characters. Discourse **about** fiction includes such utterances as 'N is a fictional character,' 'Tolstoy created N,' and 'N is a better detective than M.' Paraphrases of such sentences offered by proponents of both (b) and (c) seem implausible. However, Meinongians also have to tell a different story about the occurrence of fictional names in such contexts. Zalta (1983), for example, who has held that fictional characters, as nonexistent objects, 'encode' but do not exemplify the properties ascribed to them in the story, maintained that, in discourse about fiction, the characters do exemplify the predicated properties. Van Inwagen (1977) and Thomasson (1999) preserved the surface grammar of such occurrences of fictional names, but at the price of denying that fictional characters literally possess any of the properties predicated of them in the story: for Van Inwagen, such properties are ascribed but not possessed.

Responding to Fictions

Philosophers have also puzzled over the capacity of fictions to elicit fear or other emotions in readers. The puzzle is especially acute given the recent rise to dominance of cognitivist theories of the emotions. According to the latter, my being in an emotional state like fear requires more than that I have a certain feeling or am in a certain affective state. My fearing *x* also requires that I believe that *x* endangers me or someone close to me. Given these requirements, it seems impossible for me to experience genuine fear (or, *mutatis mutandis*, pity) concerning what is narrated in what I take to be a fiction, because I do not believe that anyone is really in danger when I imaginatively engage with such a fiction.

One strategy here is to argue that our affective responses to fictions do have the cognitive foundations required if they are to be genuine emotions. Perhaps, for example, we believe that real people are endangered or suffering **in the same way** that the fictional characters are represented as doing, and this leads us to feel genuine emotions for these real people. More plausible are analyses that take as central the belief that it is **make-believe**, in the fiction, that I stand in the relation to the fictional characters or situations required if I am to feel genuine emotions for them. According to Walton, such beliefs about the story elicit in us quasi-emotions, which resemble genuine emotions in their physiological and psychological features and which enter into our imaginative engagement with the fiction by encouraging us to **make believe** that we feel the corresponding real emotions (see also Currie, 1990, chapter 5). Neill (1993), however, contended that affective responses elicited in us through our beliefs as to what is fictionally true are often instances of genuine emotions. A third alternative is the so-called 'thought theory,' which holds that such responses (whether or not they are genuine emotions) are engendered not by beliefs about what is the case, actually or fictionally, but by thoughts (Carroll, 1990; Lamarque, 1996) or imaginings (Novitz, 1987) as to what might be the case. (See Hjort and Laver, 1997, for further articles.)

Figurative Language: Semiotics

F Nuessel, University of Louisville, Louisville, KY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The term 'figurative language' can be misleading because it has at least two meanings. For many years, texts on literary criticism have used this expression to mean a literary adornment or a stylistic device (Wellek and Warren, 1956: 23, 157). Lakoff and Johnson (1980: 3) noted this conventional usage in their influential work on metaphor. In general, the expression 'figurative language' was restricted to special usage in poetry or rhetorical language. Traditional scholars maintain a strict dichotomy between figurative language and ordinary or literal language. This conventional aesthetic sense of figurative language no longer reflects current usage. Today, the term 'metaphor' has replaced 'figurative language' with the special sense of a cognitive device used to explain how people categorize reality and store abstractions of that physical existence in their brain.

In this article, we will discuss the following issues:

1. Theories of metaphor
2. A selected overview of theoreticians of metaphor and their theories
3. The literal-figurative dichotomy
4. The role of metaphor as a cognitive mechanism
5. The use of metaphor as a knowledge generator.

The literature about metaphor is voluminous, as exemplified selectively in three extensive bibliographies on this topic (Noppen and Hols, 1990; Noppen *et al.*, 1985; Shibles, 1971). Moreover, important journals devoted to metaphor, such as *Metaphor and Symbol* (formerly, *Metaphor and Symbolic Activity*), *Poetics*, and *Cognitive Linguistics* reflect this burgeoning interest.

The explosion of literature on metaphor reflects some basic shifts in linguistic theory during the 20th century. In particular, there have been three philosophical revolutions in linguistic theory. In the first part of the 20th century, the North American linguist Leonard Bloomfield (1887–1949) espoused what he called a mentalist approach to the study of language in his book *Introduction to the study of language* (1914). Subsequently, Bloomfield would undergo a philosophical transformation while at Ohio State University under the influence of the behavioral psychologist Albert Weiss (1879–1931). This theoretical conversion appeared in Bloomfield's classic volume *Language* (1933). This behaviorist, or empiricist, view of language received its maximum articulation in B. F. Skinner's (1904–1990) *Verbal behavior* (1957). Its stunning repudiation by Noam Chomsky (b. 1928) in his review in the journal *Language* in the same year represents the beginning of the Cartesian, or rationalist, approach to linguistic theory that continues to be vital today. Neo-empiricism, however, reasserted itself in the influential book *Metaphors we live by* (1980) by George Lakoff (b. 1941) and Mark Johnson (b. 1949).

Traditional discussion of figurative language features a detailed typology of figures of speech. It was a standard practice for those who studied Greek and Latin to receive training in the tropes (derived from Greek for 'manner') of literary language. These include metaphor, simile, personification, and others.

Introduction

The term 'figurative language' can be misleading because it has at least two meanings. For many years, texts on literary criticism have used this expression to mean a literary adornment or a stylistic device (Wellek and Warren, 1956: 23, 157). Lakoff and Johnson (1980: 3) noted this conventional usage in their influential work on metaphor. In general, the expression 'figurative language' was restricted to special usage in poetry or rhetorical language. Traditional scholars maintain a strict dichotomy between figurative language and ordinary or literal language. This conventional aesthetic sense of figurative language no longer reflects current usage. Today, the term 'metaphor' has replaced 'figurative language' with the special sense of a cognitive device used to explain how people categorize reality and store abstractions of that physical existence in their brain.

In this article, we will discuss the following issues:

1. Theories of metaphor
2. A selected overview of theoreticians of metaphor and their theories
3. The literal-figurative dichotomy
4. The role of metaphor as a cognitive mechanism
5. The use of metaphor as a knowledge generator.

The literature about metaphor is voluminous, as exemplified selectively in three extensive bibliographies on this topic (Noppen and Hols, 1990; Noppen *et al.*, 1985; Shibles, 1971). Moreover, important journals devoted to metaphor, such as *Metaphor and Symbol* (formerly, *Metaphor and Symbolic Activity*), *Poetics*, and *Cognitive Linguistics* reflect this burgeoning interest.

The explosion of literature on metaphor reflects some basic shifts in linguistic theory during the 20th century. In particular, there have been three philosophical revolutions in linguistic theory. In the first part of the 20th century, the North American linguist Leonard Bloomfield (1887–1949) espoused what he called a mentalist approach to the study of language in his book *Introduction to the study of language* (1914). Subsequently, Bloomfield would undergo a philosophical transformation while at Ohio State University under the influence of the behavioral psychologist Albert Weiss (1879–1931). This theoretical conversion appeared in Bloomfield's classic volume *Language* (1933). This behaviorist, or empiricist, view of language received its maximum articulation in B. F. Skinner's (1904–1990) *Verbal behavior* (1957). Its stunning repudiation by Noam Chomsky (b. 1928) in his review in the journal *Language* in the same year represents the beginning of the Cartesian, or rationalist, approach to linguistic theory that continues to be vital today. Neo-empiricism, however, reasserted itself in the influential book *Metaphors we live by* (1980) by George Lakoff (b. 1941) and Mark Johnson (b. 1949).

Traditional discussion of figurative language features a detailed typology of figures of speech. It was a standard practice for those who studied Greek and Latin to receive training in the tropes (derived from Greek for 'manner') of literary language. These include metaphor, simile, personification, and others.

This classical view of figurative language as the adornment of a basic literal language influenced literary research and analysis. Wellek and Warren's *Theory of literature* (1956) embodied this approach, and it was highly influential in university literature departments.

Conventional courses in literature often have a component on rhetorical or figurative language. These discussions view such language as stylistic in nature and designed to arouse the reader's interest through these embellishments. The following is a selected enumeration of some conventional tropes (cf. Danesi and Perron, 1999: 162–164 for a more extensive list).

Theories of Metaphor

Most theories of metaphor can be reduced to two basic ones with some variation. In this section, we will examine these theories and some of their most prominent proponents. First, there is the comparison theory, which may be traced back to the Greek philosopher Aristotle (384–322 B.C.). In this model, metaphor has the form *A is B*, and it suggests an analogy between two items or notions. In this view, a metaphor is a compressed simile. This is the traditional approach, and it includes the resemblance of objects or notions; its usage involves style or economy of statement. A variant of the comparison theory is the substitution theory. The substitution theory means that an inappropriate (figurative) term stands for a proper (literal) one. In this approach, the speaker uses an expression that means, or refers to, something else, thereby requiring the listener to decode the statement. An example is *Martin Luther King is a lion*. *Lion* thus substitutes for the meaning that Martin Luther King is brave and fearless. The essence of the comparison model or the substitution version is based on the premise that there is a basic literal language that is precise and neutral. This language stands in stark contrast to the poetic language generally associated with literature and rhetorical flourishes.

The second major theory is the interactionist theory, which, with its various manifestations and modifications in the 20th century, is the prevailing one today. It contrasts with the comparison view of metaphor. In this approach, there is an interaction of concepts at sentence-level and not word-level, i.e., there is a conceptual association of the elements that constitute a metaphor, and this association gives rise to new meaning as we shall see.

Selected Review of Theories of Metaphor

In this section, we will examine selectively prominent theoreticians of metaphor. These include Aristotle, Giambattista Vico, Groupe μ, I. A. Richards, Max Black, Paul Ricoeur, George Lakoff, and Mark Johnson.

Aristotle (384–322 B.C.)

Aristotle is credited with introducing the word 'metaphor' in two of his major treatises (*Rhetoric* and *Poetics* [1997]). The etymology of the word metaphor is from the Greek 'to carry beyond' or 'to transfer.' This meaning refers to an implied comparison or transference of meaning between two objects formulated as 'A is B' or 'A implies B.'

Aristotle's view of metaphor is a literalist one, i.e., metaphors stand in contrast to ordinary language. Moreover, his view of metaphor is now known as the comparison theory of metaphor, i.e., 'A is B' or 'A implies B.' Aristotle's influential statements about language and rhetoric in *Rhetoric* and *Poetics* continue to be cited after more than two millennia.

Table 1 Some examples of traditional figurative language

Type of figurative language:	*Definition:*
Conceit	An analogy between two completely distinct notions, e.g., *war is peace*.
Euphemism	Use of a pleasant word for one that is vulgar or obscene, e.g., *powder room for toilet*.
Hyperbole	Extreme exaggeration, e.g., *he ate half a side of beef*.
Irony	Sarcastic wit to mean the opposite of what is meant, e.g., *I love that dress!* (meaning, *I hate that dress!*).
Litotes	Understatement to magnify the significance of a statement, e.g., *Verdi was not an unimportant composer*.
Metonym	A common feature is used to designate the whole entity, e.g., *the pen is mightier than the sword*.
Onomatopoeia	The use of words to describe the sounds that they refer to, e.g., *the clanging of the bells*.
Oxymoron	An observation that is apparently contradictory, e.g., *he is a wise fool*.
Paradox	An apparently contradictory statement, e.g., *dumb as a fox*.
Personification	The representation of a concept or an object as living entities, e.g., *Death came through the door*.
Rhetorical question	A question that is not intended to be answered, e.g., *do you understand me?*
Simile	An overt comparison with words such as *like* or *as*, e.g., *he floats like a butterfly*.
Synecdoche	The part stands for the whole, e.g., *the law* (= *the police*) *broke down the door*.

The Greek philosopher, and student of Plato (ca. 428–347 B.C.), considered metaphor in *Poetics* (Aristotle, 1997: 150–156). In a general discussion of grammar and etymology, Aristotle provided selected observations on metaphor. In particular, Aristotle stated that "metaphor is the transference of a word of another significance either from genus to species, or from species to genus, or from species to species or by analogy or proportion" (Aristotle, 1997: 150). Aristotle (1997: 151) stated that there are four types of metaphor. His consideration of the first three was terse, while his commentary on the fourth was a bit more expansive.

Aristotle's first type, that of genus to species, is the expression "my ship stands there" (Aristotle, 1997: 151). In this type of metaphor, which is, in fact, a synecdoche, 'stand' is the genus and 'lying at anchor' is the species.

The second type (species to genus) offered by Aristotle (1997: 151) is "verily ten thousand noble deeds hath Odysseus wrought," in which case 'ten thousand' signifies 'many.' Again, this is a synecdoche, and some critics have labeled it 'clumsy' because the choice of 'ten thousand' to mean 'many,' even though it may have been a commonly accepted expression in Aristotle's time, is definitely not novel.

The third metaphor type, and the exemplar for species to species is "with the blade of bronze drawing out the life" (1997: 151) and "cutting with the unwearied bronze" (1997: 151). In these cases, 'drawing out' means 'cutting.' while 'cutting' means 'removing something.' Both mean to 'take away.' Umberto Eco (b. 1932) argued that this third type of metaphor was the quintessential one on which subsequent theories base their own views of the nature of metaphor (1984: 92). Aristotle's third type of metaphoric exemplar perhaps best illustrates 20th-century views of metaphor as a tripartite concept, e.g., I. A. Richards's (about whom more will be said below) notion of a metaphor as consisting of a tenor (the metaphorized term), a vehicle (the metaphorizing term), and a ground (the meaning created by the interaction of the tenor and the vehicle. This type of metaphor has the form (A (B) C), i.e., A is the tenor, C is the vehicle and B is the ground or the intermediary term which provides the meaning of the metaphor supplied by the interpretant, or the person who seeks to make meaning of the comparison. The tenor (often called the topic now) is the A-referent (what is talked about in the metaphor). The vehicle is the C-referent (something concrete or familiar) and the ground is the meaning of the comparison, or the B-referent. In the sentence, *Mary is a witch*, 'witch' is the vehicle, 'Mary' is the tenor or topic, and the meaning created by the connection of these two terms is the ground. Cultural context will assign a specific meaning to the vehicle of a metaphor.

The fourth and last type of metaphor, with Aristotle's overt statement that it is by analogy or proportion, involves a formula with four elements. Aristotle offered two examples. The first is the analogy of the "shield of Dionysus" and the "cup of Ares" (Aristotle, 1997: 151). In this four-part proportional metaphor, the four terms may be delineated in the following way as a subject/instrument relationship: Dionysus : cup :: Ares : shield. This is to say that 'shield of Dionysus' is a metaphor for 'cup,' and 'cup of Ares' is a metaphor for 'shield.' Thus, the cup is to Dionysus as the shield is to Ares. Eco (1984: 95) pointed out that there are similarities and differences in this metaphor. Dionysus and Ares are both gods (the former of joy and peaceful rites, the latter of war and death). The cup and shield are alike due to their roundness. The hearer must pick out the similarities and discard the differences. If there are too many differences, the metaphor is unsuccessful.

In Aristotle's second example (Aristotle, 1997: 151), "old age [is] . . . the sunset of life," attributed to Empedocles (5th century, B.C.), there is a proportion or analogy that consists of four terms, namely, A : B :: C : D, i.e., old age : life :: sunset : day. This proportion is different from the above metaphor because it involves the proportion A : B :: C : D. In this metaphor, the proportion may be stated in the following way: A = old age, B = life, C = evening, D = day. In this sense, A is to B as C is to D. Hence this proportional analogy is a comparison of the life cycle to the diurnal cycle.

Thus, in a succinct narration, Aristotle provided us with our initial knowledge of the metaphor, and one to which all future scholars would refer over the millennia. Aristotle's views on metaphor contain three basic notions: (1) there is an exchange of properties between two entities to increase understanding; (2) there is a cognitive dimension to metaphor, albeit suggested rather than overtly stated, and Aristotle does not explain this; and (3) the pair metaphor/metonymy represents the essence of semiosis and human thought.

It is also clear that Aristotle left a legacy that includes a doctrine of signs, when he observed that words are tripartite objects which consist of a form (pronunciation), a referent (what the word alludes to), and a meaning. In one of his statements on metaphor, Aristotle (1997: 153) stated that ". . . making good metaphors requires the ability to grasp resemblances." In effect, this observation is a comparison model of metaphor. Aristotle's comparison theory has met with criticism over the centuries, though its basic premise remains intact.

It should be noted that the Roman rhetorician Quintilian (ca. 35–100 A.D.) espoused Aristotle's comparison view of metaphor and claimed that it was a substitutive process. This substitution theory argued that in the metaphor 'John is a rat,' the use of 'rat' for 'man' (in the sense of a vile and loathsome creature) was simply a deviation from a pristine literal language. Neither Aristotle nor Quintilian offered a psychological explanation for the pervasive use of metaphor in world languages. That would not take place in any systematic way until the 20th century.

Giambattista Vico (1668–1744)

The Neapolitan empiricist philosopher had many interesting things to say about metaphor, and his observations presage important work in the 20th century, and it is for this reason that we discuss his work here. In his treatise *The new science* (1968), Vico spoke about figurative language, in particular, metaphor. Reawakened interest in Vico in the 20th century corresponds to a renewed interest in metaphor research and the way in which Vico conceptualized it. Vico differs from his rationalist counterpart, the French philosopher René Descartes (1596–1660), whose views on language are quite distinct. Descartes was a rationalist who believed that people possess an innate linguistic faculty rather than an acquired one.

Vico's views on language consist of a series of basic epistemological principles that propose how we acquire knowledge about the world and how language develops. His stance on language in general, and metaphor in particular, may be stated as axioms about the origination of language and thought. We will now discuss this set of stages or steps in the development of thought and language, and, ultimately, metaphor.

First, thought is corporeal. We acquire our knowledge of the external world through our senses. In this regard, Vico espouses his empiricist view of epistemology by arguing that our knowledge has a sensory basis, i.e., we learn about the world by experiencing it first and foremost through vision, as well hearing, touch, smell, and taste. We then use this information to categorize this knowledge in a systematic way through our contact with the external world. Second, thought is representational. This means that it is imaginative or image-creating. These visual, culturally-determined patterns allow us to access information retained in our memory iconically. The linguist Ann Viberg noted that in the languages of the world, most of the predicates that are synonymous with the verbs of knowing and understanding relate to visual intake. In fact, prior to the development of a systematic language system with a phonology, morphology, syntax, semantics, and lexicon, it is likely that prelinguistic peoples utilized visual signals and signs including primitive pictures for communication as evidenced by the drawings and paintings at various archaeological sites worldwide, e.g., the cave paintings of Altamira, Spain. Third, thought has gestalt (German for configuration)-like properties, i.e., it consists of segments or parts that have a greater significance than its individual constituents. This axiom means that we configure thought through a series of components that build from the concrete to the abstract. Fourth, thought has an ecological basis. For Vico, human language evolved through a series of stages that included gestures that stood for a single article (tool) or concept (fire), and these symbolic gestures developed over time into complex verbal systems. Finally, thought and its verbal manifestation speech is, in fact, metaphorical in nature. For Vico, the process by which thought and language developed means that language is metaphorical, because we express ourselves through categories based on real-world experience, which we internalize in our brain in meaningful components.

The essence of Vico's cognitive scientific views of metaphor appears in the following citation "...in all languages the greater part of the expressions relating to inanimate things are formed by metaphor from the human body and its parts and from the human senses and passions. Thus, the head for top or beginning; the brow and shoulders of a hill..." (Vico, 1968: 129). This association of external reality with the bodily experiences of that reality is the essence of the new empiricist linguistics which was encapsulated in Lakoff and Johnson's (1980: 59) observation that "...we typically conceptualize the nonphysical *in terms of* the physical...." i.e., the unknown in terms of the known.

I. A. Richards (1893–1979)

Richards introduced some basic notions on the structure of metaphor in his classic treatise *The philosophy of rhetoric* (1936). In the fifth and sixth lectures ('Metaphor' and 'The command of metaphor') of the Mary Flexner Lectures series at Bryn Mawr University, he discussed metaphor in revolutionary terms. In his fifth lecture, Richards (1936: 90) noted that metaphor has traditionally meant "...a grace or ornament or *added* power of language, not its constitutive form." In this groundbreaking paper, Richards would go on to espouse his interactionist theory of metaphor. He argued, in fact, that metaphor is ubiquitous in language, and, by implication there is no literal-figurative speech dichotomy. Richards then introduced new expressions for the three parts of a metaphor, namely, 'tenor,' 'vehicle,' and 'ground.' In a prototypical metaphor, the tenor is the topic or the unknown part in Richard's triadic configuration.

The vehicle is the part that comments on the topic, and the ground is the actual meaning created by the interaction of the tenor and the vehicle.

In this theoretical model, Richards builds upon Aristotle's claim that metaphor is the comparison of two apparently dissimilar items (*A is B*) or the substitution of one item for another (*A stands for B*). In Richards' model, however, there is an interaction, i.e., parts of the two entities remain separate and distinct but there is a domain of shared properties in which a new meaning is created. This area of shared properties may be configured as (A(X) B). In this model, A is the tenor (topic) or the unknown aspect of the metaphor. B is the vehicle that is a familiar object or concept. X in the equation just given is the ground or meaning produced by the association of the tenor (A) and the vehicle (B). Thus, the previously mentioned statement *John is a rat* causes the hearer to think or experience one thing in terms of another. In this case, we are invited to draw comparisons between the behavior and traits of a person (*John*) and those of an animal (*rat*). Clearly, a human and a rat are distinct, yet they may share certain traits, e.g., animate, furtive, sneaky, filthy, to name but a few domains of similarity. It is in these areas that new meanings are created. In this specific case, the prototype metaphor or conceptual metaphor (see Lakoff and Johnson below) is PEOPLE ARE ANIMALS (conceptual metaphors are presented in upper case letters by convention and we will follow this format throughout). The specific case here causes the hearer or reader to draw inferences about the shared properties of *John* and a *rat*. To be sure, the similarities in this instance are not pleasant ones. We can thus state that *John* is the tenor or topic, *rat* is the vehicle, and the ground is the meaning of this metaphor, i.e., the conceptualization of John as a vile person. The juxtaposition of the A component (tenor/topic) and the B component (vehicle) is thus responsible for an interaction that provides a new meaning that had not previously existed. Although Richards uses the term 'interaction' in his writing on metaphor, this expression would be most closely associated with Max Black (see below) who gave it currency.

As we shall demonstrate, scientific discovery relies heavily on the use of metaphor to create new knowledge about the world by this interactionist strategy. Many scientific breakthroughs have occurred by using this epistemological strategy, e.g., William Harvey's (1578–1657) use of the machine metaphor to describe the physiological phenomenon of the movement of the valves of the heart.

Richards (1936: 92, 93) also points out that metaphor is "omnipresent" in speech. He notes that even in scientific and technical language, metaphors are ubiquitous. Although Richards did not carry out an empirical analysis of this assertion, Pollio and his associates (1977) did just this, and they discovered that novel and dead metaphoric language permeated speech. Richards thus takes the position that there is no literal-figurative dichotomy, i.e., the claim that there is a basic 'ordinary' language that is embellished by the use of colorful figurative language.

In yet another way, Richards is a precursor of the theoretical metaphorology espoused by George Lakoff and his advocates. He states that thought is metaphoric. By this, he means that metaphor constitutes the essence of epistemology. We acquire knowledge about our world and ourselves by converting concrete experience into abstract manipulable units of that experience that allow us to categorize it and refer to it.

Max Black (1909–1988)

Max Black provides another perspective of the interactionist view of metaphor. In his illuminating discussion on the form of metaphor (Black, 1981 [1955]: 77–78), Black enumerated seven basic points about the interaction model of metaphor. First, a metaphor consists of two topics, a primary and a secondary one. Next, these topics are not monolithic entities, but rather they are complex, well-organized groupings of properties. Third, the metaphor affixes to the primary topic a complex of analogous insinuations attributable to the secondary topic. Fourth, in general, these inferences involve commonalities, though, occasionally, there are startling associations. Fifth, metaphors are selective in their implications, i.e., they choose only certain aspects of the secondary topic that apply to the primary one. Sixth, transformations in the lexical meaning belonging to the same family may be metaphoric transfers. Finally, no simple rule for shifts in meaning exists, nor is there a good explanation for why some metaphors are accepted and others are not.

Schroots (1991: 222) best captured the essence of Black's interactionist view of metaphor in the following observations:

1. Metaphors are concerned with systems of ideas;
2. Such systems are specially constructed;
3. Metaphors are projective in that they allow one field of thought (subject) to organize another, whether by selection, filtering, focusing, or other means; and
4. Models are extended and systematic metaphors.

The celebrated semiotician Charles Peirce (1839–1914) espoused the concept of 'abduction.' Simply

stated, this is an educated guess. With regard to metaphor, abduction allows the hearer to make a meaningful association between the tenor (now generally called the topic) and the vehicle, i.e., the A and the B components of a metaphor. Abduction would thus allow the hearer to engage in meaningful hypotheses about what the associations between the tenor and the vehicle might be. As noted above, if the associations are tenuous or oblique, then the metaphor will be unsuccessful.

Groupe μ

Groupe μ consists of a cadre of scholars at the University of Liège in Brussels who published *A general rhetoric* (1981) that dealt with figurative language. It predated Lakoff and Johnson's groundbreaking work on metaphor but offered an excellent overview of a structuralist approach to metaphor research. This group represents the ideology of Ferdinand de Saussure (1857–1913), Louis Hjelmslev (1899–1965), Emile Benveniste (1902–1976), Algirdas Julien Greimas (1917–1992), Roman Jakobson (1896–1982), and others of the Structuralist school (see more about this linguistic school below).

Paul Ricoeur (1913–2005)

Paul Ricoeur's study (1977) of metaphor is considered to be one of the major statement on metaphor. In this important volume, Ricoeur authored eight essays on metaphor. Ricoeur appropriately began with a consideration of Aristotle's views as the prime mover in metaphor research for more than two millennia. Next, he reviewed the French writer Pierre Fontanier, whose taxonomic approach was inadequate to explain metaphor. In his third study, the author examined metaphor as a sentence-level or a word-level device. In his fourth and fifth studies, Ricoeur investigated structuralist views of metaphor. The sixth study moved to the discourse-level of metaphoric analysis. The seventh paper discussed reference, and the final one dealt with the philosophical underpinnings of metaphor research. What makes this volume valuable is the author's ability to analyze the multiple approaches to metaphor in an objective fashion. Ricoeur brought to our attention that the study of metaphor means coming to grips with the essential nature of language – meaning and semantic deviation.

George Lakoff (b. 1941) and Mark Johnson (b. 1949)

Lakoff and Johnson articulated an elaborate theory of metaphor as a cognitive construct. Their collaborative and individual work has done much to advance metaphor research in the past quarter century. In this section, we shall devote an extended discussion to their contributions to metaphorology.

In *Metaphors we live by* (1980), Lakoff and Johnson discussed the notion of the conceptual metaphor. Their approach to the study of metaphor is now known as Conceptual Metaphor Theory. Thus metaphors such as the previously stated example *John is a rat* (discussed previously) is part of the general conceptual metaphor which equates qualities of people with qualities of animals. Sometimes, these are positive (*Mary is a bunny rabbit*), and in other instances they are negative (*John is a warthog*). The preceding three examples belong to the conceptual metaphor PEOPLE ARE ANIMALS.

Conceptual Metaphor The conceptual metaphor PEOPLE ARE ANIMALS is relatively common. In recent times, the generic term predator, those animals that live by preying on other, weaker animals for sustenance, has come into frequent use. Predatory animals include, but are not limited to, lions, tigers, and pumas. When people are labeled as predators, this is a subcategory of the PEOPLE ARE ANIMALS conceptual metaphor. This type of metaphor is common in the media, especially when referring to certain types of heinous crimes. This metaphor involves those people who prey upon people who are weaker, e.g., children, older adults, or people with disabilities. The following sentences illustrate this usage.

1. The man *stalked* his victim for days.
2. The outlaws *hunted* their prey surreptitiously.
3. The criminal *pursued* his quarry relentlessly.

The sense of this subcategory of PEOPLE ARE ANIMALS is decidedly negative, because it evokes powerful negative emotions due to its unpleasant associations. Conceptual metaphors thus consist of two parts that are called domains. The first is a source domain (vehicle, or the known, sometimes labeled the B-referent) and a target domain (tenor or topic, or the abstract element, sometimes called the A-referent). In the PEOPLE ARE PREDATORS conceptual metaphor, *people* is the target domain, or the topic itself, while *predator* is the source domain, or the vehicle that delivers the metaphor to the hearer. A metaphor is thus the mapping of one domain into another.

In the Lakoff and Johnson model, metaphor is not a mere deviation from an underlying literal language that functions as a linguistic ornament. Rather, metaphor is now viewed as a cognitive process that allows the mapping of a source to a target domain to enhance comprehension of the unknown in terms of the known. Thus, for Lakoff and Johnson (1980: 5, emphasis in original) "the essence of metaphor is

understanding and experiencing one kind of thing in terms of another."

Other examples of conceptual metaphors include the ARGUMENT IS WAR metaphor, exemplified by such common examples as the following sentences.

ARGUMENT IS WAR

1. They *fought* my claims constantly.
2. I *won* that point.
3. They *beat* us in court.

An additional illustration of conceptual metaphors follows. It should be noted that many of these are rooted in the proverbial language of a culture. In English, 'time is money' is simultaneously a proverb and a conceptual metaphor.

TIME IS MONEY

1. We will *buy back* your time with release time.
2. *Budget* your time for each section of the test.
3. *Donate* some of your free time to this cause.

The number of conceptual metaphors in a language is potentially unlimited. Different cultures, however, will focus on and highlight different aspects of these metaphors.

Metonymy A subcategory of metaphor is metonymy. Metonymy refers to the use of one element to refer to another that is closely related. The following examples illustrate this cognitive mechanism.

1. He loves *Cervantes*. (Cervantes = the writings of Cervantes)
2. She's in *opera*. (opera = the profession of operatic performance)
3. *New hair* made John very happy. (new hair = surgical procedure to implant hair).

Synecdoche Synecdoche is a subtype of metonym. It is the conceptual process by which the part stands for the whole, i.e., a segment of an object stands for the entire object. The following examples depict this cognitive device.

1. The *SUV* is destroying the environment. (= the overuse of the this type of vehicle is destroying our limited natural resources)
2. A few good *arms* will help us win this baseball game. (= good pitchers will help the team to win the baseball game)
3. The *brains* in that university are world-class. (= the intelligent people on the faculty).

Marcel Danesi (1946–) and Paul Perron (1940–) introduced the expression 'conceptual metonym' as a parallel to conceptual metaphor as a way to organize reality in different cultures (1999: 176). Conceptual metonyms are another meaning-making tool at our disposal. Among the categories they suggest are the following ones.

PRODUCER FOR THE PRODUCT

1. Give me a *Perrier*®.
2. I just bought a *Ferrari*®.
3. I own a *Miró*.

THE PLACE FOR THE INSTITUTION

1. The *White House* just denied complicity.
2. *Fleet Street* is predicting a recession.
3. *Vatican City* issued a papal decree.

During the decade of the 1980s, Lakoff and Johnson presented a persuasive model of metaphor to explain how we convert concrete experience into abstract concepts and store the information gleaned from those experiences in our brains. In the next section, we shall discuss how Lakoff and Johnson described this process.

The Image-Schema The image schema is a key element in the theoretical construct of Lakoff and Johnson's conceptual metaphor. Johnson (1987: 29) pointed out that an image schema "...operates at a level of mental organization that falls between abstract and propositional structures ... and particular concrete images...." Johnson argued that in order for us to provide structure to our experience and to be able to recall it, there has to be a pattern and order in our perceptions, actions, and conceptualizations. This arrangement occurs through image schemas that consist of shapes, patterns, and images that provide regularity to our experience. Schemas allow us to categorize and catalogue our experienced reality by associating the unknown with the known and allowing us to decide where the new information belongs. The experimental psychologist, Eleanor Rosch (1973), showed that people do this on a regular basis. In this way, conceptual metaphor, and its related forms conceptual metonymy and conceptual synecdoche, represent this cognitive process.

Johnson pointed out that the image schema is not a photographic reproduction of experienced reality; rather, it is a mental icon that is malleable in its format, i.e., is not a fixed form. It allows us to fit new experiences into a somewhat amorphous pattern or shape and give it meaning. Image schemas may represent any of the five senses (sight, hearing,

touch, taste, smell). Selected linguistic analogues include the following expressions:

1. A sight to behold (sight)
2. The roar of the crowd (sound)
3. A clammy feeling (touch)
4. A sweet flavor (taste)
5. The smell of greasepaint (smell).

Because image schemas are such an ingrained part of language, we often do not recognize them.

Lakoff's (1987: 122–124, 138–142) work on fuzzy grammar pointed out systematic grammatical reflexes of what would come to be called image schemas. Lakoff showed that English utilizes certain phrases and expressions to express membership in prototypical categories. Thus, there are certain objects that clearly belong to a specific category, e.g., birds (winged, feathers, ability to fly) such as cardinals and bluejays. Other animals either do or do not belong to this category or belong only marginally. In these cases, expressions such as *a kind of*, *sort of*, *essentially*, and many more are employed to situate these objects at the periphery of this category. Thus, the sentence *a penguin is a kind of a bird* indicates our placement of this animal at the border of this image-schematic classification. Ronald Langacker would develop this notion to a far greater extent in his 'cognitive grammar' model of linguistic theory (see below).

Lakoff and Johnson's innovative research thus represents a continuum in the analysis of metaphor dating back to Aristotle. They utilize pre-existing scholarship as the basis for their conceptual metaphor theory. At the beginning of the 20th century, researchers such as Karl Bühler (1879–1963) initiated experimental research in the paraphrasing of metaphor-rich proverbial language. By the middle of the 20th century, psychologists including Charles Osgood (1916–1991), B. F. Skinner (1904–1990) and Solomon Asch (1907–1996) began to examine metaphor. It was I. A. Richards and Max Black, however, who most influenced Lakoff and Johnson's research with their interactionist view of metaphor.

Ronald W. Langacker (b. 1942)

The theoretical linguist, Ronald W. Langacker, articulates Lakoff and Johnson's views on conceptual metaphor in his cognitive grammar. Langacker notes that the Lakoff and Johnson view of metaphor is one in which metaphor is basic to epistemology. As stated previously, metaphor involves mapping a source domain (vehicle = the known) and a target domain (topic or tenor = the unknown). In this approach, the projection of a source field onto a target field is a metaphoric process. In this sense, as Danesi and Perron (1999: 175) noted that metaphor is "...the ability of the human brain to convert experience into abstraction via the mapping of some source domain onto a target domain to produce an abstract concept." In his extensive research, Langacker provides specific examples from various languages to illustrate how his version of cognitive grammar works. What Langacker does is connect the conceptual metaphors to grammar. Specifically, he relates grammatical categorization and concept formation. The following example illustrates Langacker's line of argumentation.

Lakoff demonstrates that certain aspects of English grammar reflect the image schema, the essential basis for Lakoff and Johnson's notion of the conceptual metaphor. Langacker (2002: 1–32) showed a relationship between grammar and concept formation. In cognitive grammar, a metaphorical theory of grammar, we receive input from the external world. This input is processed at the experiential level, i.e., through our senses. Next, this information is converted into image schemas such as shapes and so forth. Third, the image schemas are transformed into conceptual metaphors/metonyms/synecdoches. Finally, this totality of information is transformed into the linguistic categories of grammaticalized or lexicalized forms.

A succinct, albeit simplified restatement of one example, of the many presented by Langacker (2002: 149–163) suffices here. The verb *go* exemplifies the grammaticization, or the projection of certain basic concepts into the grammar of a language. The verb *go* has the meaning of motion and, subsequently, it evolves into a future meaning. This occurs because the original meaning of 'movement from the speaker,' a spatial concept, is transferred to a temporal domain. On the one hand, this verb means to move from point A to point B, e.g., A → B. On the other hand, it signals a more abstract movement through time, i.e., an activity that will be carried out at a future time. In this sense, English and many other languages of the world combine spatial and temporal movement into a single verb. To be sure, this explanation is a bare-bones discussion of the complexities involved this semantic shift from space to time, but it serves to show that conceptual frameworks may be grammaticized or shifted from experience to an abstract grammatical notion of movement.

Literal Versus Figurative Language

The assertion that figurative language derives from a basic literal language has been a matter of discussion

for some time. This underlying assumption thus separates language into two distinct categories – one primary, the other secondary. For nearly 25 centuries, since Aristotle's commentary, the assumption of the literal-figurative language dichotomy has gone virtually unchallenged, albeit certain philosophers such as Vico have indeed insinuated that all language is metaphorical. As noted above, Aristotle's significant statements about metaphor held sway, with certain precursory and insinuative statements to the contrary, until the 20th century.

The essence of the literal-figurative debate revolves around whether or not metaphor is a deviation from some pristine ordinary language or whether it is a basic form of linguistic expression. The essential question relates to whether or not metaphor is derivative or basic. To respond to this question, it is necessary to consider briefly some hypotheses about the origin of language. In this regard, Danesi (1993: 1–29) discussed in some detail the likely, lengthy progression of the process of linguistic evolution. Danesi's response was Vichian in that he subscribed to Vico's empiricist view that language originates through gestures that signified basic concepts. Subsequently, these isolated gesticulations and primitive interjections became codified into an ever-increasing abstract set of oral symbols that we call language. This process involves an abstraction or a metaphoricization of these primitive experiences that evolved from gesture to symbolic utterance to a fully developed linguistic syntax. Many of these primal metaphors become unrecognizable and they now appear to be literal linguistic expressions. Because these basic metaphors have become so commonplace and are now unrecognizable, we assume that they are literal.

In the literalist camp, Mac Cormac (1985: 73) defined literal language as "the use of language to express concrete objects and events. When we employ ordinary words in their ordinary dictionary senses to describe events or situations that are publicly perceptible, we are speaking literally." Even though Mac Cormac is an ardent literalist who believes that there is a distinction between these two forms of language, he conceded that as a literal language apologist, he (Mac Cormac, 1985: 78) must admit that his explication of literal language presupposed an elementary metaphor, namely, that the world consists of natural categories.

In his 1936 discussion of metaphor, Richards was among the first to break with tradition and state that metaphor is essentially omnipresent in language. By making this bold statement, he revolutionized prevailing wisdom about metaphor. It is no longer deviation from standard or literal language, it is, in fact, the essence of language. Richards noted that the boundary between literal and figurative language was not fixed or constant.

Empirical research carried out by Pollio *et al.* (1977), for example, provided persuasive evidence for what Richards called the omnipresent nature of metaphor in ordinary language. Specifically, their research showed that individual speakers uttered approximately 3000 new metaphors per week, as well as 7000 idioms that are frozen metaphors.

Lakoff disputed the literal-figurative dichotomy. In an important article on this aspect of language, Lakoff (1986: 292) pointed out various distinct meanings of literal language. It is possible to state Lakoff's views of the misconceptions of the word 'literal' in this debate in at least four different ways. First, literal language diverges from special uses of language such as literary language. Second, there is a language for a particular subject matter. Third, there is a language that has no secondary meaning. Finally, there is a logical language that may be true or false. Lakoff points out that these four basic assumptions of a literal-figurative dichotomy are not tenable. In fact, the four meanings of 'literal' converge.

Semiosis and the Signifying Order

The signifying order is the means by which a society or a culture codifies meaning. It is a tripartite process, as Danesi and Perron (1999: 70) pointed out. It consists of semiosis (the capacity to comprehend and create signs), representation (the process of using signs to refer to objects and concepts), and the signifying order (the cultural complex employed by a given culture to impose representation and order in that society).

Sebeok (1920–2001) developed a modeling system to describe this process of the comprehension and production of signs (Sebeok, 1994: 116–127). The primary modeling system is the mental system that receives input from the external world. This system is the one that underpins the representational operations of replication, simulation, imitation, and indication. Next, the secondary modeling system is that mental system that produces projections of primary or concrete models into abstractions. In this sense, language exemplifies this modeling system because it utilizes primary signs to create linguistic signs. The tertiary modeling system extends primary and secondary modeling systems into an elaborate schema of cultural signs (literature, the performing and representational arts) to its most abstract and significant levels. The combination of these three systems, and most especially the tertiary modeling system is metaphorical, in nature because the cultural signs stand for different aspects of the culture, e.g., an Italian opera

is a higher order system of signs (verbal, musical, artistic) that incorporates many essential aspects of the Italian culture.

Metaphor production is a special example of this process that involves, as Danesi and Perron (1999: 69) discussed, a series of stages that includes environmental input into the bodily senses through a process of semiosis. This input is then represented in the mind and ultimately displayed in the culture through the signifying order. In language and in art, this signifying order manifests itself through metaphoric concepts. The actual activity of sign-making is re-presentation, i.e., the presentation knowledge and information again in some new symbolic format, e.g., writing, painting, sculpture, architecture, and so forth. There is an ordered process for semiosis, namely, external input (through the senses) → re-presentation (the use of signs to refer to these external stimuli) → culture (the culture in which person lives gives meaning to the signs of that culture). One of the roles of educating a child is to teach it the salient signs of a culture. Parents engage in this activity with their children from infancy on. The signs of a specific culture are both verbal (language) and nonverbal (kinesics, paralanguage, proxemics). Cultural signs are transmitted from one generation to another via literature, and the plastic and representational arts. Oral societies use memorized and recollected narratives, a kind of auditory cultural history to transmit their cultural signs from one generation to another. These codified signs must be learned by members of other cultures. In the deaf community often via various forms of translation, these signs take the form of meaningful systematic visual gestures.

The essence of semiotics, as Sebeok (1994: 11) pointed out, is the relationship expressed in the medieval Latin expression *aliquid stat pro quo,* i.e., 'something stands for something else.'

Charles Sanders Peirce would expand this bipartite definition (object-sign) of the sign to a tripartite one, in which interpretation becomes the third element (object-sign-interpretant). In essence, a sign is generally considered to consist of three components: (1) the sign or representation (something employed to stand for something else); (2) the object or referent (what is referred to by the sign); and (3) the interpretant (a person's understanding of the sign-object relationship, determined by culture). Medical analysis, one of the oldest recorded professional practices, provides a good example of this triadic system of meaning. In classical medicine, the four signs of illness were *fervor* 'fever,' *dolor* 'pain,' *rubor* 'redness,' and *tumor* 'swelling.' These signs or symptoms, alone or in combination, stand for various physical maladies to be interpreted by the physician. Over the years, symptomatology has become quite sophisticated, in part, aided by new knowledge and sophisticated technology. A good example of the medical sign is the aggregation of symptoms that stand for a stroke, namely, sudden numbness or weakness of the face or limbs, especially on one side, confusion, vision problems, and so forth. All of the medical signs converge to form a systematic pattern of a particular medical problem. The correct interpretation of this cluster of meaningful signs results in a diagnosis. The grouping of physical signs stands for specific illness or syndromes as interpreted by a trained physician.

The Uses of Metaphor

Metaphors may generate new knowledge. As noted above, this is often the case in science. The ability to explain the unknown in terms of the known, the abstract in terms of the concrete, make them ideal vehicles to expand knowledge and to enhance comprehension.

In any discussion of metaphor as a knowledge creator, especially in science, it is necessary to discuss three basic notions: (1) analogy, (2) model, and (3) metaphor. It is not uncommon to find these terms used interchangeably, though, in fact, they are distinct. Analogy, a term used by Aristotle in the definition of his fourth type of metaphor, has at least two meanings. First, it may mean similarities in two objects that are otherwise distinct. Secondly, it is a kind of inference by which it may be deduced that objects that bear some similarity may also be comparable in other ways. A model in the scientific sense does not refer to a scale model, but rather to an analogy. A metaphor in science is again a comparison of the unknown in terms of the known. Thus, a miniature planetary system stands for the Bohr-Rutherford atom, a container of billiard balls in motion for the kinetic movement of gases, the computer for the brain, and so forth.

A model may be an object, often of reduced scale, that stands for the actual object. In architecture, scale models of buildings are commonplace. A second meaning is a tentative theoretical construct intended to function as a testing device. In her discussion of 'model,' Mary Hesse (b. 1924) uses the example of the dynamic model of gases, in which gases are seen as an assortment of billiard balls in random motion. In this model, motion and impact are the shared features, while color, hardness and shininess are irrelevant (Hesse, 1966: 7–11). The shared elements are a positive analogy; those that are not significant constitute a negative analogy. Other factors that play no role in the analogy are neutral. In this view of a 'model,' the primary model ($model_1$) alludes to the

imperfect copy (billiard balls) minus the negative analogy. The second use of the term 'model' ($model_2$) is the second copy with its positive, negative, and neutral analogies.

A few examples of a model are in order. The Bohr-Rutherford conceptualization of the atom is explained in terms of the planetary system, i.e., the different parts of the atom with its component electrons and protons which function much as the planets that revolve around a central solar system. In this case, the planetary system is $model_1$ and the Bohr-Rutherford atom is $model_2$. Additional examples of this use of modeling include comparisons of the human or animal body to a machine, or the brain to a computer.

We shall now discuss a number of specific examples of how science and education use metaphors and models as a way to advance knowledge. It must be noted that a model is an actual object (planetary system, billiard balls, computers) already known to the audience. The theory used to explicate the scientific innovation uses the model metaphorically, once again, to describe the unknown in terms of the known.

Theory-Constitutive Metaphors

Scientists use metaphors to explicate their theories in a way that will make them comprehensible to their intended audience. This public, however, is often limited to fellow scientists. Successful metaphors, i.e., those that introduce a novel perspective in a branch of science, tend to capture the imagination of an entire generation of scholars who embrace its basic meaning and apply its newly created insights to previously unresolved problems. This notion of theory-constitutive metaphor merits review at this juncture.

Thomas S. Kuhn's (1922–1996) book *The structure of scientific revolutions* (1970) argued that there are periods of normal science when scientists work within a single paradigm or model commonly accepted by the practitioners of a particular science until there is what many call a 'breakthrough.' In his discussion of paradigm, Percival (1976: 286–287) noted that scientific paradigms consist of symbolic generalizations, such as Einstein's $e = mc^2$, which are elegant, yet simple explanations for previously unexplained phenomena. Paradigms also consist of models or conceptual analogies that offer members of a given scientific community an ontological framework. Members of these groups share theoretical values to evaluate competing theories within their framework. Finally, they use exemplars to show how their theory resolves complex problems that earlier theories could not. Periodically, this normal science is rejected, most often by a single scientific genius who provides answers to residual problems in the prior theory as well as making significant new strides in the field of inquiry. What we shall see is that scientific revolutions are often founded on novel metaphors that reject those of the theory they have supplanted.

Linguistics 20th-century linguistic theory provides an excellent example of the use of metaphor to change theory. During the last century, two major theoretical paradigms in linguistics emerged. The first was exemplified by Leonard Bloomfield's *Language* (1933), with its empiricist view of language. In this book, linguistic knowledge derives from external sensorial experience. In *Verbal behavior* (1957), B. F. Skinner, the U.S. psychologist, elaborated these empiricist views on language through his stimulus-response approach, one that greatly influenced second-language education in the 1960s. A second theoretical approach to linguistic analysis emerged with Noam Chomsky's *Syntactic structures* (1957) and *Aspects of theory of syntax* (1965), and its clearest exposition in Chomsky's *Cartesian linguistics* (1966), with its rationalistic approach to language acquisition, i.e., humans are born with an inherent language acquisition device.

Both of these linguistic theories employ distinct metaphors. In brief, the Bloomfield model, or American Structural Linguistics, language may be viewed as a stack of boxes that represent levels of analysis (phonology, morphology, syntax). The linguist begins with the lowest box, or level, and then, presumably utilizes a series of analytical tools (item and arrangement analysis, item and substitution analysis) until the highest level (syntax) is attained. It utilizes a down-up metaphor. This approach utilizes the empiricist notion that language is accessible and analyzable through the senses. Structuralism likewise introduces language as a physical, biological, organic entity. Hence, phonemes functions as atoms, syllables as molecules, and words as cells, though it was rare that structural analysis went beyond these linguistic units to higher order linguistic units such as sentences and discourse. Again, analysis starts with the phoneme, or basic unit of sound in a language, since its metaphoric model were those sciences which progressed from the smallest unit to the largest one. The conceptual metaphors that guided structural linguistic analysis, as we shall see, are very different from that those organized transformational-generative linguistic theory.

One of the problems with the structuralist model, and one that the next generation of linguists would address in a comprehensive fashion, is its failure to provide an analysis of syntax. In the succeeding generation, the transformational-generative model of

language, Noam Chomsky viewed language as an abstract system genetically embedded in the brain. In this model, syntax is central, while phonology and morphology are lower-level, somewhat superficial manifestations of the abstract syntactic level. In this theoretical model, the brain functions as a computer, and it generates an infinite number of grammatical sentences via a limited set of simple rules. This model employs a left-right metaphor for analysis (rewrite rules). Transformational grammar also uses the metaphor of a tree structure with terminology such as branching, pruning, chopping, and nesting to describe its processes. Finally, geometrical and mathematical metaphors predominate, e.g., mapping, transforming, and propositional calculus. It is this use of mathematical metaphors that caused some to believe that the transformational-generative model of linguistic theory was a branch of mathematics. In the transformational model, ideas are often described as 'parallel,' 'diametrically opposed,' and 'central.' The fact that Western culture has a predisposition to accept mathematical and scientific models of the world as objective and authentic is another reason for the switch from structuralism to a generative-transformational model of language.

An essential element of Chomsky's theory of language involves the computer metaphor. Several scholars observed that the computer metaphor is one that prevails when speaking of the mind or brain. Boyd (1979) examined this usage in his analysis of cognitive psychology. Boyd (1979: 360–361) made several equations including the following: (1) thought = information processing; (2) brain language = computations; (3) memory = data storage capacity; and (4) consciousness = feedback. Many of these same analogies exist implicitly in Chomsky's early work such as *Syntactic structures* (1957) and explicitly in his later work *The minimalist program* (1995) where, in fact, his language comes directly from computational jargon. It must also be noted that there are significant differences between the human brain and a computer as well as limitations on both.

Linguistics utilizes theory-constitutive metaphors to elucidate its basic principles. When there are significant changes in these metaphors, there is a paradigm change in the way linguistic theory examines its basic topic of study – language.

Physics Physics uses metaphor to explain and illustrate theories that would otherwise be difficult to comprehend. In his discussion of the metaphoric notion *boojum* (Mermin, 1990), N. David Mermin (b. 1935) points out that this expression derives from Lewis Carroll's (pseudonym of Charles Lutwidge Dodgson, 1832–1898) nonsense poem 'The hunting of the snark.' What Mermin wanted to do was describe the physical properties of a certain type of liquid at very low temperatures. At these low temperatures, the expected patterns could not be maintained, and as was the case with the snark, the physical behavior "softly and suddenly vanished away" (Carroll, 1939: 778). The neologism and the concept are now an established part of physics, as evidenced by its appearance as an entry in *Webster's new international dictionary*. Mermin's use this metaphor captures the essence of the physical properties of this phenomenon.

Anatomy Sir William Harvey (1578–1657), whose anatomical research revealed the circulation of blood throughout the body, employed a mechanistic metaphor to illustrate his findings. In his description of the auricles and ventricles of the heart, Harvey likened them to the firing of a projectile from a firearm. To be sure, his description is incomplete but compelling.

Second Language Pedagogy Second language pedagogy is replete with metaphoric constructs, many of them implicit. For Herron (1982), second language methodology consisted of a series of shifting metaphoric models. The grammar-translation model, for example, employs the MIND-BODY metaphor, by which second language acquisition entailed a sort of mental exercise akin to bodybuilding. A second metaphorical model, THE PRODUCTION METAPHOR, was characteristic of audiolingualism. In this approach, the process of imparting a second language to a student is similar to a factory in which a supervisor (instructor) molds the products (students) through their blueprints (textbooks). The basic purpose of this approach was a utilitarian one, in which use of the fundamental language skills (speaking, writing, comprehension, and reading) were the primary goals. The production metaphoric model still lingers in career-oriented classes, i.e., language for specific purposes (medicine, law, social work, and so forth). Herron also noted that a new metaphoric model has emerged; namely, that second language acquisition is the same as first language acquisition. One effect of this metaphor is to make the teacher a parent in the classroom, and this frequently results in a teacher-dominated classroom environment. Metaphoric models, especially unrecognized ones, may have a negative effect on second language instruction because they bear assumptions that may be counterintuitive to the results sought. Danahy (1986) concurred in this assertion and categorized metaphoric models for second language instruction and student-teacher interaction using major divisions – human-non-human metaphors and human-human ones. In the former case, the

culinary metaphor entails that an instructor is the actor and the students are the patients. In this active/passive model, students are the recipients of a prepared meal that will enrich and enhance them. In the latter model, the family metaphor is one that assumes that students are child-like individuals incapable of doing anything on their own. This parent-child metaphor is a powerful that prevents students from becoming independent and self-sufficient. Recognition of the metaphoric models that pervade a discipline is essential to an understanding of what we do. Identification of negative or inappropriate conceptual metaphors in any profession is a first step to remedying deficiencies.

Concluding Remarks

In this overview of figurative language, we have seen that there are two basic theories of metaphor: the comparison theory that dates back to Aristotle, and its subsidiary version, the substitution model. In the 20th century, the interactionist theory, originally articulated by I. A. Richards and Max Black, but perhaps most completely developed and elaborated by George Lakoff and Mark Johnson, provides us with a cognitive-conceptual model of metaphor and its corollaries metonymy and synecdoche to form a novel epistemological model.

Figures of Speech

Y Shen, Tel Aviv University, Tel Aviv, Israel

© 2006 Elsevier Ltd. All rights reserved.

A 'figure of speech,' sometimes termed a 'rhetorical figure' or 'trope,' is a word or group of words used in some deviation from the strict literal sense of the word(s), or from the more commonly used form of word order or sentence construction. Although traditional rhetoric distinguishes between 'figures of speech' and 'figures of thought,' it has been often difficult, in the absence of any universally accepted criteria, to differentiate between the two in any consistently accepted manner. It has been claimed, by Quintilian among others, that figures of speech are, by nature, grammatical or rhetorical (e.g., antithesis, anaphora) and as such can retain their original sense even when subject to change. This is not true with figures of thought, which, it has been argued, are expressions that have *a priori* strayed from their intrinsic, literal sense (e.g., metaphor, irony, and synecdoche).

Another oft-made distinction underlines the differences between 'schemes' and 'tropes.' Simply put, schemes are abnormal arrangements that allow ideas to be presented forcefully, while tropes are devices that alter the conventional meaning of the expression. The former includes, for example, alliteration and chiasmus, while the latter encompasses metaphors, irony, and synecdoche.

Scope and Functions

Figurative language is central to both poetic and nonpoetic discourse. Throughout the ages, figurative expressions have been featured extensively in the works of both orators and writers alike, who used them to embellish their style, to clarify or illuminate meaning in an efficient, compact manner, or as a particularly effective persuasive device.

Over the years, the study of figures of speech moved from the sphere of traditional rhetoric to that of poetics, and, more recently, to the cognitive sciences, specifically cognitive linguistics and cognitive psychology. This latter development was triggered by a growing awareness that the scope and functions of figures of speech extend well beyond the realm of traditional rhetoric or poetics. However, this view is not an entirely new perception, with scholars dating back to the classical era (for example, Quintilian, and later Alexander Gottlieb Baumgarten and Giambattista Vico) sensible to the fact that figurative modes and models lie at the heart of human consciousness and thus underlie the process of conceptualizing experience. These figurative modes include, in addition to metaphors, metonymy, synecdoche, and irony.

Studies conducted over the last 50 to 60 years have revealed that those figurative modes play an important part not just in everyday thought and language, but in the evolution of most intellectual disciplines, whether in the arts or sciences, as well (Burke, 1945; White, 1978). While traditional rhetoric assumed tropes to be exclusively verbal expressions, recent studies in the field of visual rhetoric and visual literacy have uncovered the existence of a visual equivalent to the verbal trope; hence, the concept of 'visual tropes,' which have pushed the conceptual and so functional boundaries of tropes forward to a considerable degree (Kennedy, 1982). Literary scholars (notably, the Russian formalists and New Critics) have regarded figurative language as a basic stylistic property, key to the unique nature of all poetic discourse. (e.g., Shklovsky, 1965; Mukařovský, 1970; van Peer, 1986). Students of cognitive linguistics (e.g., Lakoff and Johnson, 1980; Gibbs, 1994), claiming that figuration belongs to the realm of thought rather than language, insist that – as suggested by Gibbs in his *The Poetics of Mind* – figurative modes of thinking help to structure and mold human cognition. Accordingly, figurative modes, far from being mere verbal

A 'figure of speech,' sometimes termed a 'rhetorical figure' or 'trope,' is a word or group of words used in some deviation from the strict literal sense of the word(s), or from the more commonly used form of word order or sentence construction. Although traditional rhetoric distinguishes between 'figures of speech' and 'figures of thought,' it has been often difficult, in the absence of any universally accepted criteria, to differentiate between the two in any consistently accepted manner. It has been claimed, by Quintilian among others, that figures of speech are, by nature, grammatical or rhetorical (e.g., antithesis, anaphora) and as such can retain their original sense even when subject to change. This is not true with figures of thought, which, it has been argued, are expressions that have *a priori* strayed from their intrinsic, literal sense (e.g., metaphor, irony, and synecdoche).

Another oft-made distinction underlines the differences between 'schemes' and 'tropes.' Simply put, schemes are abnormal arrangements that allow ideas to be presented forcefully, while tropes are devices that alter the conventional meaning of the expression. The former includes, for example, alliteration and chiasmus, while the latter encompasses metaphors, irony, and synecdoche.

Scope and Functions

Figurative language is central to both poetic and nonpoetic discourse. Throughout the ages, figurative expressions have been featured extensively in the works of both orators and writers alike, who used them to embellish their style, to clarify or illuminate meaning in an efficient, compact manner, or as a particularly effective persuasive device.

Over the years, the study of figures of speech moved from the sphere of traditional rhetoric to that of poetics, and, more recently, to the cognitive sciences, specifically cognitive linguistics and cognitive psychology. This latter development was triggered by a growing awareness that the scope and functions of figures of speech extend well beyond the realm of traditional rhetoric or poetics. However, this view is not an entirely new perception, with scholars dating back to the classical era (for example, Quintilian, and later Alexander Gottlieb Baumgarten and Giambattista Vico) sensible to the fact that figurative modes and models lie at the heart of human consciousness and thus underlie the process of conceptualizing experience. These figurative modes include, in addition to metaphors, metonymy, synecdoche, and irony.

Studies conducted over the last 50 to 60 years have revealed that those figurative modes play an important part not just in everyday thought and language, but in the evolution of most intellectual disciplines, whether in the arts or sciences, as well (Burke, 1945; White, 1978). While traditional rhetoric assumed tropes to be exclusively verbal expressions, recent studies in the field of visual rhetoric and visual literacy have uncovered the existence of a visual equivalent to the verbal trope; hence, the concept of 'visual tropes,' which have pushed the conceptual and so functional boundaries of tropes forward to a considerable degree (Kennedy, 1982). Literary scholars (notably, the Russian formalists and New Critics) have regarded figurative language as a basic stylistic property, key to the unique nature of all poetic discourse. (e.g., Shklovsky, 1965; Mukařovský, 1970; van Peer, 1986). Students of cognitive linguistics (e.g., Lakoff and Johnson, 1980; Gibbs, 1994), claiming that figuration belongs to the realm of thought rather than language, insist that – as suggested by Gibbs in his *The Poetics of Mind* – figurative modes of thinking help to structure and mold human cognition. Accordingly, figurative modes, far from being mere verbal

constructs, are primarily conceptual by nature and as such play a key role in various cognitive domains, including categorization, problem solving, inferences, and memory.

Figures of Speech in the Cognitive Era

The impact of the 'cognitive revolution' on the study of figurative language was considerable. It precipitated numerous studies (as surveyed in Gibbs, 1994) suggesting that figurative modes, notably metaphor and metonymy, play a central role in structuring and shaping human cognition. Drawing on developments in the field of cognitive sciences, it encouraged students of cognitive linguistics, psycholinguistics, cognitive psychology, and others to explore in great detail and depth all manner of figurative types.

While the emphasis in classic rhetoric was on the classification (taxonomy) of tropes, the cognitive revolution encouraged scholars to delve into such questions as how figurative types work and how they are understood. This produced ever more comprehensive, yet detailed studies of the major figurative types. It led to the introduction of novel issues as well as the development of new methodologies, which, in turn, broadened the range of questions studied even further. Finally, as noted, the cognitive revolution uncovered new, previously unimagined trope-linked functions. Thanks to these developments, issues such as the employment, comprehension, and appreciation of tropes could now be explored in greater depth.

In this context two key and oft-examined questions merit particular attention: (a) how does the processing of literal language differ from processing figurative language? and (b) what is the directionality of mapping?

The Processing of Literal as Opposed to Figurative Types

In this context the key question is whether nonliteral language – metaphors, irony, metonymy, etc. – calls for forms of processing that are distinct from those used to process literal language. The standard view, rooted in philosophy of language theories and pragmatic theory (see Gibbs, 1994) – notably Searle's speech act theory and Grice's theory of conversational implicatures – is that figurative language, being an intentional violation of specific pragmatic and/or communicative norms, obliges the addressees to abide by certain procedures if they are to unearth the figurative expression's meaning. From this it follows that, prior to decoding a figure of speech's figurative meaning, its literal meaning must first be understood. In other words, the former cognitive activity is optional and pursued only after it is clear that the expression's literal meaning is in some way defective.

However, there is psycholinguistic evidence suggesting that if tropes – that is metaphors, metonymy, idioms, as well as indirect speech – are set in a likely and/or plausible context, it is possible to grasp their figurative thrust without having to first analyze and then reject their literal meaning. These experimental findings, which apply to all figurative types, including irony (see, Gibbs, 1993), do more than simply blur the distinction between the way in which literal and figurative language are processed. They suggest that, at least during the initial stages of the cognitive process, the psychological mechanisms used to decipher both literal and figurative speech are the same.

Directionality of Mapping

The question of the directionality of the conceptual mapping process from source to target domains is another key issue in the study of metaphorical and metonymic types. Figurative expressions, it is claimed, follow well-defined structural (directional) patterns. These will be described in greater detail in the following section, which discusses the major figurative types, namely the four types of metaphor (simile, oxymoron, synesthetic metaphors, and zeugma), plus metonymy and irony. This discussion will also examine the question of processing and other related topics.

There are clear qualitative differences between the four aforementioned metaphorical figures. Similes feature an explicit comparison connector. An oxymoron is comprised of two terms between which lies a vast, ostensibly unbridgeable, conceptual gulf. Synesthetic metaphors are a unique metaphorical type involving cross-sensory modality mapping. A zeugma turns on the order in which the terms within the metaphor appear.

Similes A 'simile' is based upon an explicit comparison between two terms, for example, *Rage is like a volcano*. Traditional literary and philosophical theories of simile (see, e.g., Black, 1962; Beardsley, 1958) focused principally on issues such as the difference between a metaphor and a simile, or how the comparison marker *like* serves to elucidate the simile's meaning. It was cognitive studies of similes (that is, metaphorical comparisons), notably that of Ortony (1979), that first raised the question of directionality. Were metaphorical comparisons inherently asymmetrical (that is, unidirectional), and if so, was the asymmetry characteristic of metaphorical comparisons higher than that of literal comparisons? For example, the sentence *Billboards are like placards* is

a literal comparison, since billboards and placards fall into the same category and so share a considerable number of highly salient attributes. On the other hand, the statement, *Billboards are like warts* is a metaphorical comparison, or simile, since some of the highly salient properties of *wart* match a number of the less salient attributes of *billboard*: both are ugly, protuberant, and a blight on the surroundings. This high-low salience relationship underlies all similes. Hence, Ortony contended (supported experimentally) that, in terms of similarity, the degree of asymmetry found in metaphorical comparisons was higher than that found in literal or anomalous comparisons.

Synesthetic Metaphors 'Synesthesia' (Greek, *syn* 'together' + *aesthesis* 'perception') is a remarkable psychological and linguistic phenomenon that has long fascinated scholars from a variety of fields (for a review, see Dann, 1999). In psycho-perceptual terms, synesthesia refers to the involuntary physical reaction produced by crossmodal association, such as seeing a certain color each time a particular sound is heard. 'Synesthetic metaphors,' by contrast, are a verbal phenomenon in which a concept belonging to one sensory domain is referred to in terms taken from another sensory domain. Thus, Keats' 'heard melodies are sweet' evokes a clearly auditory concept *(heard melodies*) in terms belonging to the realm of taste (*sweetness*). The expression *a cold light* is another example of a synesthetic metaphor. In this case, *light,* which is linked to the visual domain, is defined in terms of coldness, which belongs to the tactile domain. In technical terms, the synesthesia sweet melodies reflects a mapping process in which the source domain taste is mapped onto the target domain of sound, while the synesthesia *cold light* represents a mapping process whereby a word belonging to the tactile (source) domain is mapped onto a word belonging to the (target) visual domain.

One of the central issues in the study of synesthesia concerns the directionality of mapping in synesthetic metaphors employed in poetic discourse. Namely, are some modalities more likely to be mapped onto others, or are all modalities equally liable to mapping, irrespectively? Ullmann (1945) (see also Tsur, 1992) proposed a graduated scale of modalities ranging from sight – the 'highest' modality – followed by (in order of importance) sound, smell, taste and, finally, touch – the 'lowest' sense. Based on this hierarchy of senses, synesthetic metaphors embrace either a low-to-high mapping process, as in Keats's 'sweet melody,' in which the mapping progresses from the lower sensory modality of taste to the higher auditory domain, or a high-to-low directionality, as in the expression *melodious sweetness,* in which mapping proceeds from the higher auditory to the lower taste domain.

Studies of assorted poetic and prose corpora (e.g., Ullmann, 1945; Shen, 1997) – in English, French, Russian, Arabic, Hebrew, Chinese, and Japanese – revealed a marked preference for low-to-high as opposed to high-to-low directionality, with a single exception: synesthetic metaphors involving the two highest modalities, sight and sound. These findings are supported by empirical research, which has shown that it is both easier to recall, as well as to assign meaning to, low-to-high mapping constructs, which are also, as rule, regarded as more natural.

According to Shen (1997) the low-to-high pattern that is typical of synesthetic metaphors is a specific case of a more general metaphorical mapping principle, according to which mapping from more accessible to less accessible domains is generally favored over mapping from less accessible to more accessible domains (Lakoff and Johnson, 1980). In the context of synesthetic metaphors, this general cognitive principle stipulates that concepts such as touch and taste, associated with the lower senses, are more easily accessible than those related to the higher senses, for example, sound and sight. The reason that lower sensory concepts such as coldness or sweetness are more accessible is that they are generally experienced directly, unlike most higher sensory concepts, which are, as a rule, experienced at several removes. In sum, synesthesia's marked predilection toward low-to-high mapping, stemming, as it does, from the above general cognitive principle, imposes severe constraints upon the use of synesthetic metaphors in natural discourse.

Oxymoron An oxymoron (ancient Greek, *oxus* 'sharp' + *moros* 'dull' = a sharp dullness) is a figure of speech containing two contradictory concepts, as in the phrase *sweet sorrow.* The former example, like the expression *serious vanity,* contains two clearly antonymic terms, thus producing, as do all oxymora, an utterly incongruous statement.

Oxymora are ubiquitous and appear in all types of discourse. Shakespeare had a marked penchant for oxymora: "O heavy lightness serious vanity!/ Mis-shapen chaos of well-seeming forms!/Feather of lead, bright smore, cold fire, sick health!" (*Romeo and Juliet,* Act 1, Scene 1); as did Milton, for example, with his "darkness visible."

There are two types of oxymora (Shen, 1987): 'direct' and 'indirect.' The first involves 'direct' antonyms (e.g., *silent sound*), while the second involves 'indirect' antonyms (e.g., *sweet sorrow* or *cold fire*). While both semantic structures are oxymora, in the case of indirect oxymora the terms involved are

contradictory only by association (see Shen, 1987). Poetic and nonpoetic discourse in most languages has, over the ages, inclined toward the indirect rather than direct oxymora, perhaps because indirect oxymora are easier to digest than direct ones (Gibbs and Kearney, 1994).

Zeugma A 'zeugma' is a figure of speech in which one syntactic category, typically a verb or an adjective, governs a catalog of at least two other syntactic categories (normally nouns); however, it does so literally in one case and metaphorically in the other. For example: *She caught an airplane and a husband* or "Her beauty pierced mine eye, her speech my woeful breast/Her presence all the powers of my discourse" (Cuddon, 1977). As can be seen in both cases, one term (*caught* and *pierced*) stands in the same syntactical relation to two or three other terms (*airplane* and *husband* in the first instance and *eye, breast,* and *discourse* in the second), yet, in each case, it assumes a different meaning. One of the key questions relating to zeugmas, which touches, albeit indirectly, upon the subject directionality, concerns the order in which the zeugma's components are arranged. Studies (Shen, 1997) have shown there to be a marked bias, in both poetic and nonpoetic discourse, toward placing the literal component before the metaphorical one, as in *He packed his shirt and sadness*. This 'literal first' structure is, as has been observed (Shen, 1997), a cognitively simpler and more easily comprehended configuration. Certainly most people would blink twice at the construct *He packed his sadness and his shirt*.

While in metaphorical figures, the relationship between the target and source domains revolves around the highly complex notion of similarity, underpinning the two remaining figurative types of metonymy and irony is the difference between what is said and what is meant.

Metonymy Traditional rhetoric defines 'metonymy' (Greek, 'change of name' or 'misnomer') as a figure of speech in which one word is substituted for another word with which it has some kind of contiguous relationship, for example, the relationship between a container and what it contains, exemplified by the sentence *the kettle is boiling,* in which *the kettle* signifies the water it contains. In the sentence *Napoleon invaded Russia*, the word *Napoleon* stands for the *French Army*, a substitution made possible by the existence of a contiguous relationship between a leader and his army or nation.

There are several theories (Jakobson, 1971; Burke, 1945) underlining the differences between metaphors and metonymy. All essentially argue that while metaphors hinge on similarity, metonymic expressions are based on the existence of a contiguous relationship between the metonymic phrase (Gibbs, 1993) and its intended meaning. Examples of such a contiguous relationship include the relationship between the part and the whole or between cause and effect (sometimes termed 'synecdoche').

It has been suggested (Gibbs, 1993) that one reason metonymic statements are easily understood is because our conceptual system contains several metonymic models that underpin and shape most metonymic expressions. Hence, the conceptual principle in which the object replaces the user produces such metonymic sentences as *the sax* (read: saxophonist) *has flu today,* while the conceptual habit of substituting place for event results in the sentence *Watergate* (read: the bugging of the Democratic Convention by the Republicans and the subsequent White House cover-up) *changed our politics*.

Metonymy displays certain biases in terms of directionality. Thus, while authors' names are often cited in lieu of the title(s) of their book(s), for example, *Have you read Tolstoy?* there are some things that cannot be expressed in terms of the person or persons who made them: one can hardly say *Mary was tasty* with *Mary* representing the cake she baked.

Clearly there are some elements within the perceptual or conceptual domain that are more susceptible to metonymic substitution than others. Whether or not a term will lend itself to metonymic use depends on its perceptual and conceptual salience (Radden and Kövecses, 1999). Salient concepts include concepts of an immediate and direct nature, big concepts, and noticeably gestalt-like concepts. This perceptual-conceptual distinction between salient and nonsalient terms affects the metonymy's directionality, there being a marked preference for the use of immediate stimuli in lieu of nonimmediate stimuli, as in the expression *I'll answer the phone,* which actually means *I'll answer the person speaking at the other end of the line*. There is also a tendency to favor dominant over less dominant terms. Hence, metonymic expressions will name the biggest and most powerful country in the system or the principal part of the country in lieu of the larger geopolitical unit: England for Great Britain or Russia for the former Soviet Union. This principle may also explain why generic terms such as *mankind* or *postman* are traditionally masculine in form.

Irony In 'irony' (Greek, *eironeia* 'dissimulation,' principally by understatement) the relationship between what is said and what is meant is utterly

at odds. This gives the speaker the freedom to exaggerate or understate matters and to be sarcastic, sardonic, or cynical at will. For example, when people respond to a particularly stupid action by saying *That was very clever,* the positive turn of phrase is in direct contradistinction to the obviously negative reaction to the affair. It is this discrepancy between what is said and what is meant that makes irony a nonliteral or a figurative type. The expressed meaning and the intended meaning of ironic statements are not simply different but diametrically opposed, which distinguishes irony from all other figurative types.

The use to which irony is put also differentiates it from its fellow figurative types. Rather than purporting to express the nature of something, irony is primary intended to express the speaker's attitude (typically negative or critical) toward that something (Gibbs, 1993). It differs from plainly literal critical attitudes in that it is indirect – therefore, less confrontational. Irony also serves to 'echo' expectations or offer an alternative view of a given situation. For example, the expression *It's a lovely day,* when said in the middle of a downpour, is a way of acknowledging, indeed underlining, the utter discrepancy between the expectation that it would be a nice day and the inclement reality. The notion of 'echoing' spawned the 'Echoic mention theory' (Sperber and Wilson, 1981), according to which some statements have no nonliteral meaning but are intended simply to trigger in the listener the memory (echo) of some familiar propositions (whose truth value is irrelevant) and/or reflect the speaker's attitude toward these.

As can be seen from the above examples, in the case of irony the literal utterance is always more positive than the underlying true meaning. This pattern of directionality, which hinges on the speaker's attitude toward the subject at hand, is typical of most ironic statements (Gibbs, 1993). Recent studies on the way in which irony is understood have suggested that it takes no longer to decode an ironic remark, such as *He is a fine friend,* than it does to grasp the same sentence in a literal context, or comprehend its straightforward (un-ironic) equivalent (*He is a bad friend*) (Gibbs, 1993).

In conclusion, the poetic and ordinary use of figures of speech illustrates the two-sided nature of linguistic creativity in general. Their use represent in many cases some deviation from their nonfigurative counterparts; however, this deviation is itself highly constrained by certain (cognitive) principles. This adherence to (cognitive) constraints guarantees the interpretability and communicability of these figurative types.

Fiji: Language Situation

P Geraghty, University of the South Pacific, Suva, Fiji

This article is reproduced from the previous edition, volume 3, p. 1224, © 1994, Elsevier Ltd.

Fiji is a multilingual country in which about 95% of the population are members of either the Fijian or the 'Indian' ethnic group. Before the constitutional changes of 1987 the Indian ethnic group was slightly the larger. A number of varieties of Fijian and a number of languages/language varieties of Indian (both Indic – especially Eastern Hindi and Bhojpuri – and Dravidian) provenance are found in Fiji. In addition to these, Rotuman, a language closely related to Fijian, is spoken on Rotuma (a small island about 300 miles to the north of Viti Levu) as well as in Fiji proper, by a total of about 10 000 people. Fijian and Rotuman belong to the Oceanic branch of the Austronesian language family. Small numbers of speakers of other Oceanic languages (principally Ikiribati, or Gilbertese) and Tongan are also to be found in Fiji.

Vernacular Fijian varieties are classifiable as either Western Fijian or Eastern Fijian. Western Fijian is spoken in the western half of the major island of Viti Levu and on neighboring smaller islands while Eastern varieties are spoken in the eastern half of Viti Levu, on the other major island of Vanua Levu, and on the many small islands to the south of Vanua Levu. Standard Fijian, based on a form of Eastern Fijian, is the lingua franca of members of the Fijian ethnic group. Pidgin Fijian, a simplified form, may be used as a means of communication between Fijians and Indians, as may Pidgin Hindustani/Fiji Bāt, a simplified contact language that developed, like Pidgin Fijian, on the sugar plantations.

The principal first language of the Indian ethnic group(s) is Fiji Hindi/Fiji Hindustani. A high proportion of Fiji Indians and Fijians have a knowledge of English. A declining proportion of the Indians maintain their traditional languages (mainly Indic languages of North India). The major written language of the Indian ethnic group is Hindi/Urdu with Hindi predominating (since about four-fifths of Fiji Indians are Hindus).

English, the language of the administrators of the colonial period (1874–1970), has official status and is now the principal inter-ethnic lingua franca; it is now the first language of some city dwellers of non-European origin as well as that of most of the roughly 20 000 citizens of 'European' and 'part-European' ethnic origin. Several varieties of Chinese are maintained among the few thousand people of Chinese ethnic origin.

In the first few years of education, teaching is in a form of Fijian or Hindi/Urdu, depending on the locality, after which English is used. In the mass media, English, Fijian, and Hindi/Hindustani are the main languages used, both in broadcasting and in newspaper publication.

Fijian

P Geraghty, University of the South Pacific, Suva, Fiji

© 2006 Elsevier Ltd. All rights reserved.

Fiji is situated in the Southwest Pacific, between the Solomon Islands and Vanuatu in the west and Tonga and Samoa in the east, but closer to the latter. There are approximately 100 inhabited islands, with a population of 800 000.

Two hundred years ago, the vast majority of the inhabitants spoke Fijian. Today, Fijian is spoken as a first language by the indigenous population of 400 000 and by maybe 10 000 people of mixed ancestry and descendants of Solomon Islanders and other immigrants. Fijian is also spoken in migrant communities in New Zealand, Australia, United States, and Canada.

Fijian is a continuum of some 300 distinct but related 'communalects' divided into two major subgroups, the Western in western Vitilevu (the main island) and adjoining islands, and the Eastern elsewhere. Communalects from different subgroups are not mutually intelligible, and even within each subgroup, geographical distance presents difficulties. However, the term 'Fijian' usually refers to Standard Fijian (popularly called 'Bauan'). Fijian belongs to the Central Pacific subgroup, which also includes Rotuman and all Polynesian languages. Central Pacific is a subgroup under Eastern Oceanic and then Oceanic in the Austronesian language family.

Fijian was not traditionally written and was first recorded by European visitors in the early nineteenth century. A Roman-based alphabet was devised by Methodist missionaries around 1840 and has remained in use relatively unchanged.

Although English is the main language of education, government, and commerce, Standard Fijian has a literary tradition going back over 150 years and is used to some extent in education and in the media (three radio stations and two weekly newspapers, but minimal television programming). Although Fijian speakers are mostly literate, they use their literacy very little, with literacy in English being emphasized in schools. The 1997 constitution declared Fijian one of the official languages, along with English and Hindi.

The phoneme inventory consists of 20 consonants (b [^{m}b], c [ð], d [^{n}d], dr [^{n}r], f, g [ŋ], j [ʧ], k, l, m, n, p, q [^{ŋ}g], r, s, t, v [*β*], w, y, z [^{n}dZ]) and 10 vowels (a, e, i, o, u, ā, ē, ī, ō, ū). There are no consonant clusters, and syllables are open (except in some recent loans). In writing, vowel length is not usually marked, but most modern reference works use a macron.

Grammatical functions are typically performed by affixes or pre- and postposed particles. Pronouns distinguish four persons (including first-person inclusive and exclusive) and four numbers (singular, dual, paucal, plural). Some nouns (mostly denoting body parts and kin) are suffix possessed; others suffix a possessive pronoun to a preposed marker indicating whether the possessor eats, drinks, owns, does, or is affected by the head noun. The attribute follows the noun.

There is obligatory pronominal SVO marking of subject and object within the verb phrase. It is unusual for both subject and object noun phrases to occur outside the verb phrase, but when this happens, SVO, VSO, and VOS are equally common:

era boro-ya na cauravou na no-dra vale
they paint-it the young-men the poss-their house
'The young men are painting their house'

The popular myth among linguists that 'Fijian is a VOS language' seems to have its origin in an editorial decision made by the translator of the Bible (who was not a native speaker).

Fillmore, Charles J. (b. 1929)

D Stein, Heinrich-Heine-Universitaet Düsseldorf, Duesseldorf, Germany

© 2006 Elsevier Ltd. All rights reserved.

Charles J. Fillmore received his Ph.D. in Linguistics at the University of Michigan in 1961. After spending ten years at Ohio State and one year at the Center for Advanced Study in the Behavioral Sciences at Stanford, he transferred to the Linguistics Department at Berkeley. He was elected Fellow of the American Association of Arts and Sciences in 1984 and was President of the Linguistic Society of America in 1990.

Fillmore's work centers around interconnected foci of research. The major focus is the interface of syntax and semantics, concentrated on the analysis of English and Japanese with an emphasis on the semantics, in the broadest sense, of individual expressions. Fillmore has successfully applied this type of analysis to several types of discourse, focusing especially upon the deictic potential of individual expressions; for example, he has made use of literary discourse as a means of explaining the perspective exploited especially by modern literary discourse, such as indirect free style. His analysis of semantics and syntax was later elaborated upon in a systematic way in the form of 'construction grammar,' the integrated description of the semantics and syntax of subsentential units.

Fillmore's work has had a major impact on semantic and syntactic analysis by arguing for a separate level of analysis for 'case roles' such as agent, patient, and locative, in an effort to account for the semantics of sentences and the semantic interdependencies, manifested syntactically, between constituents, much in the vein of valency theory. Although there are regular correspondences with syntactic functions of phrases like subjects and objects, such as that between syntactic subjects and agents, these case roles have to be set up as a logically separate layer of semantic intuition and, consequently, of linguistic description, since in other cases, and in variant typological scenarios, the only argument for the association of case roles with syntactic function is based upon statistical tendencies of various strengths.

Fillmore's work constitutes a significant contribution not only in terms of linguistic theory, but also to the linguistic description of English and Japanese. The application to a major corpus of English (based on the British National Corpus, amongst other materials) of his descriptive approach is at the center of a major corpus-based lexicographic project ('Frame Net') with the aim of a semantic-syntactic description of the lexical units of English. These lexical units are conceived of as triple layers of information: a semantic case (such as agent), a grammatical function (such as subject), and a phrase type (such as NP). The semantics of a lexical unit, in particular each individual sense of a polysemous unit, is conceived of as based on a semantic frame with a script-like inferential structure associated with types of situations, objects, or events. Any target so characterized is also characterized by dependents that are part of this frame. The core elements of a particular frame uniquely specify the particular sense of a lexical unit. Meaning differences between different senses of polysemous items are reflected in different kinds of syntactic realizations of the elements of the frame defining the whole lexical unit. The aim is to ultimately provide an on-line-accessible database that contains all the semantic-syntactic information a native speaker possesses of a lexical unit.

Finck, Franz Nikolaus (1867–1910)

K A Klar, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Franz Nikolaus Finck had a comparatively short, but richly productive, academic career. The best overview of the outward trajectory of his career is given by his one-time student John P. Harrington in his 1910 *American Anthropologist* obituary. Finck "was born at Krefeld in 1867. He studied at the universities of Munich, Paris, and Marburg, receiving his doctor's degree at Marburg in 1896. He was docent in comparative philology at Marburg University from 1897 until 1901. His connection with Berlin University began in 1903; at that institution he was first docent and later professor of General Linguistics. From 1907 he was also in charge of the department of Oceanic languages in the Oriental Seminary at Berlin" (Harrington, p. 724). He had five years of military service prior to commencing his university studies, and published three small volumes of poetry during that time.

During the last year of his formal studies at Marburg, Finck "[tore] himself free from the restraints and artificialities of university life," in Harrington's words (Harrington, p. 725). He spent that year living on the Aran Islands (Ireland), conducting field work on the local Gaelic dialect, a sojourn that resulted in publication of a grammar and a lexicon. While a docent at Marburg, Finck immersed himself in the study of a great variety of languages, including non-Indo-European ones, preferring lesser-known idioms and remote dialects. Following Gaelic, he studied Gypsy (Romani), Armenian, and several Caucasian languages. He was not content to merely pursue languages in a philological mode, but employed on-site field technique (the value of which was enhanced by the recent introduction of the International Phonetic Alphabet) and made extended visits to the native regions of the speakers of languages that drew his interest. As Harrington recounted, "... during this Marburg period Finck lived among the gypsies, learning their language and customs" (Harrington, p. 725). Each of these field interludes resulted in publications. He also published articles on Polynesian and Bantu languages.

Finck is widely, if not frequently, recognized as an early influence on studies of language typology. Among his most important works are *Der Deutsche Sprachbau als Ausdruck deutscher Weltanschauung* (1899), *Die Klassifikation der Sprachen* (1901), *Die Sprachstämme des Erdkreises* (1909), and *Die Haupttypen des Sprachbaues* (1910). Not only was his scholarship informed by knowledge of a broad reach of languages; there is evidence that his thought was developing all the time. Petr Sgall noted that between 1899 and 1910, "F. N. Finck changed his attitude" regarding whether language types were rigidly fixed or not.

Despite his untimely death (due to heart disease) in 1910 during what Harrington called "the period of his most fruitful activity" (Harrington, p. 274), he left a rich record of his wide-ranging interests and insightful attention to linguistic detail. A complete bibliography can be found in Harrington (1910).

Fingerspelling

R L Sutton-Spence, University of Bristol, Bristol, UK

© 2006 Elsevier Ltd. All rights reserved.

The Relationship between Fingerspelling and Sign Languages

Manual alphabets consist of a series of handshape arrangements corresponding to the letters of a written alphabet. Using these manual letters, a signer may spell out a representation of any written word. Fingerspelling is thus the manual representation of the orthography of a word. It was originally devised by hearing people who, for various reasons (such as secrecy or vows of silence), needed an alternative to speech. However, it has been used by Deaf people for centuries. When used by Deaf signers, it is one of several ways in which sign languages may borrow forms from spoken languages in order to realize them in a visual modality. Some fingerspelled forms have become established loans in sign languages, but fingerspelling is only one resource available to sign languages, and most signs in most sign languages are created through visual motivation and are entirely independent of spoken languages. While fingerspelling is always derived from the written mode of a spoken language, the phonological patterning of sign languages may affect the ultimate form of a fingerspelled word.

Manual alphabets and fingerspelling are used only in sign language communities whose members have some degree of literacy in a spoken language, so there is a close relationship between fingerspelling and education. Since the 16th century, educators of Deaf children have used fingerspelling as a way of representing spoken languages visually (Bonet, 1620; Holder, 1669) and providing a link between signed and spoken languages (Figure 1). It has been used to support teaching methods that make no use of visually motivated signs (which may be termed 'Oral'). In some cases it was used to supplement speech and lipreading, while in others it has been the sole method of communication. Even the great 18th-century Oralist educator, Samuel Heinicke, at the Leipzig school, made use of fingerspelling (Buxton, 1886; Arnold, 1888). It has also been used to supplement teaching that uses sign languages (which may be termed 'manual') and is used in bilingual education for Deaf children. In some sign languages that use a one-handed manual alphabet, educators have used manual letters to manipulate the language, creating 'initialized signs' (see the section 'Established Lexical Items Originating from the Manual Alphabet').

Manual Alphabets

One-handed manual alphabets are the most commonly used in the world's sign languages today. In these alphabets, letters are made with one hand, in a range of different handshapes, with varying palm and finger orientations and movements. One-handed alphabets were certainly in use in Europe in religious communities in the 15th century, and a version of one of these came to be used by Spanish teachers with Deaf pupils. It was taken up (with modifications) by the French educators in the mid 18th century, and spread with the French education methods across Europe and to the Americas and, from there, across Africa, Asia, and Australasia. The International manual alphabet (selected by the World Federation of the Deaf for use in international situations) is based on these one-handed manual alphabets.

Despite the present-day dominance of one-handed manual alphabets, there are also many documented two-handed manual alphabets, in which the two hands are configured together to create manual letters. The origins of the two-handed alphabets are unknown, but examples have been documented in the former Yugoslavia, Indonesia, Grand Cayman, Germany, Norway, the USA, and the British Isles.

One-handed manual letters require many different handshapes in order to create 26 distinct configurations. Consequently, several of the handshapes are highly marked (and do not occur in non-fingerspelled signs) and motorically complex, requiring fine movements of the fingers. The small changes in finger position between letters require the fingers to be in the center of the observer's visual field. The observer's focus is on the signer's face, so fingerspelling is made

Figure 1 Juan Pablo Bonet (1620): extract from *Reducción de las letras y arte para enseñar á hablar los mudos.*

close to the body, at shoulder height. Two-handed manual letters require far fewer handshapes, because the use of the second hand permits several configurations of the same handshapes (so all handshapes in the British manual alphabet, for example, also occur in non-fingerspelled signs). As the handshape differences are less fine and the movements are larger, signs may be seen in peripheral vision, so two-handed fingerspelling is located at the waist.

Historical Changes in Manual Alphabets

The manual alphabets used in Britain have been of two basic types. Prior to 1698, most were 'arthrological,' based on methods of allocating letters to joints of the fingers or areas of the hands and pointing these out in succession (although for a few letters in some manual alphabets, a letter was represented by a given hand arrangement). In the later, 'dactylological' systems, the letters were distinguished by different handshapes, often reflecting the shapes of the written letters, as they are today.

John Wilkins's book on cryptography (1641:116) mentioned fingerspelling as one method of "secret discoursing, by signes and gestures." In one passage, he described an arthrological system, including the five vowels exactly as the vowels are made in the modern British manual alphabet (Figure 2). The alphabet presented by George Dalgarno (1680) used the same technique (Figure 3). The most substantial shift from arthrology to dactylology occurred in 1698, with the anonymous publication of *Digiti Lingua*, which presented the first manual alphabets with most letters represented by distinctive hand arrangements (Figure 4). The vowels, however, remained at the tips of the fingers, as with previous alphabets. The author recommended the use of the manual alphabet for anyone incapable of speech but made no explicit reference to its use by Deaf people. This alphabet was made within the prevailing tradition of cryptography

Figure 2 John Wilkins (1641): Mercury: the Secret and Swift Messenger (reconstructed from his description).

Figure 3 George Dalgarno (1680) Didascolocophus.

and the political turmoil in England at the time, which increased the need for covert activity. In the name of secrecy, the author offered two sets of 26 hand arrangements arranged into alphabets, with the recommendation that the reader should allocate different letters to the different handshapes, or even make up new ones.

In 1720 Daniel Defoe published *The life and adventures of Mr. Duncan Campbell*, which contained a plate showing an alphabet that is very similar to the modern alphabet (although J was missing), with only four other letters different from those used today (Figure 5). Thus, somewhere between 1698 and 1720, the British manual alphabet became fixed in roughly the form we know it.

The British two-handed manual alphabet spread to many parts of the world with the British Empire. Today some educated urban Deaf people in India who know English use the British system when fingerspelling, although the vowels are unlike the British ones. Carmel (1981) reported that South Africa and countries of the British Commonwealth used the British fingerspelling. Uganda, for example, uses the British manual alphabet, although American-initiated education programs have increased the influence of the one-handed alphabet (*Manual of Ugandan signs*, undated). In Australia, the British two-handed alphabet has been used in all states (except Western Australia, which at one time used the one-handed alphabet but later changed over to create unity in the country). Irish priests and nuns opened schools for the Deaf in New South Wales, bringing with them the one-handed Irish alphabet and creating a situation in which Catholic Deaf used one-handed fingerspelling and Protestant Deaf used two-handed (Carmel, 1981). Most of Canada uses the American one-handed alphabet, but British two-handed fingerspelling is still used in some parts of eastern Canada, and many older signers in the United States are familiar with the two-handed alphabet (Loew *et al.*, 2000).

The Function of Fingerspelling

Fingerspelling permits signers to borrow from spoken languages, and code-mix and code-switch between the signed and spoken languages, as it allows them to represent the spoken language vocabulary and morphology manually. As almost all Deaf signers who fingerspell are bilingual to some extent, it is not possible to test for distinctions between loans and code mixing (or nonce and established loans), on the grounds that loans are used only by monolinguals. It is often difficult to know when a form from English is an established loan and when it is an instance of code mixing or a nonce loan. However, some loans must be considered established loans, purely on the grounds of their widespread use within the sign language.

Fingerspelling violates essential rules of sign language phonology, primarily because natural signs rarely use more than two handshapes, whereas a fingerspelled sign may be made up of several different handshapes (representing each letter of the word). In order to more closely approximate the patterns of the recipient language, loan fingerspellings are usually abbreviated to two (or three) letters. Short words particularly (e.g., j-a-m, s-o-n, or m-a-y) may become established loans through fingerspelling. Patterns of abbreviation vary, but common processes in British Sign Language allow selection of first and last letters (e.g., b-l from *Bristol*), first and second letters (e.g., a-b from *Aberdeen*), and first letters from each morpheme (or perceived morpheme) of the loanword (e.g., m-c from *Manchester*). The selection of letters is also influenced by the form of the manual letters – at least in two-handed alphabets – so that symmetrical letters and those with a larger area of contact between the hands are more likely to be retained. Vowels are most frequently omitted, unless they are word-initial (Sutton-Spence, 1994).

Fingerspelling may be of entire content words, especially of proper nouns and of nouns referring to new

Figure 4 Anonymous (1698) *Digiti Lingua.*

concepts. Signers working with a spoken language interpreter may sometimes fingerspell a word to ensure that the interpreter produces the English word that the signer has in mind. Function words may also be fingerspelled. As most sign languages express grammatical relations through space rather than lexically, these function words are often noticeable as loan items, but their short length makes them formationally easy to assimilate to the sign language phonology.

Established Lexical Items Originating from the Manual Alphabet

Initialized signs are signs that are usually visually motivated in the location and movement path of the hands, but the handshape of the manual letter corresponding to the initial letter of the spoken language equivalent is imposed upon the sign. For example, in American Sign Language, a sign with a visually motivated location and movement path symbolizing a 'pathway' may be made with different handshapes from the manual alphabet, using a 'W' handshape to mean *way*, a 'P' handshape for *path*, 'R' for *road*, 'S' for *street*, 'A' for *avenue*, and so on.

The nature of two-handed manual letters prevents their widespread use in initialized signs (with the exception being the letter C, which is made with one hand and which does lead to initialized signs). Instead, in British Sign Language, single manual letter signs may be made by using a simple repetition of the first letter of the corresponding English word. Thus,

Figure 5 Attributed to Wallis (mid to late 17th Century) by Jussen (1973). From Defoe (1720) *The life and adventures of Mr. Duncan Campbell.*

signs meaning *mother*, *Monday*, *member*, *minute*, and *month* may be made with a repeated letter M, and *George*, *ginger*, *government*, *garage*, and *Gloucester* may all be made with a repeated letter G. Context and an accompanying mouth pattern derived from the spoken English word serves to specify the meaning of the sign.

Finland: Language Situation

D Nelson, University of Leeds, Leeds, UK

© 2006 Elsevier Ltd. All rights reserved.

Finland lies at the northeastern extremity of Europe, a linguistic and political boundary zone that has shaped the language situation of the country. Two languages have official status, Finnish and Swedish. Archaeological evidence shows continuous settlement in Finland for at least 8000 years, but linguistic data for these very early populations is scarce.

Until the 17th century, indigenous Saami speakers, traditionally engaged in reindeer-herding, hunting, and fishing, inhabited roughly the northern two-thirds of Finland. Since then, the Saami have been gradually displaced northward and have undergone cultural and linguistic assimilation. At present, Saami speakers make up about 0.03% of the population and include about 2000 North Saami speakers, 300 Skolt speakers (originally resettled from Russia after 1944), and 250 Inari speakers (Ethnologue 2000). All Saami speakers in Finland are bilingual and relatively few speakers are children, but some revitalization programs are in place. The 1992 Saami Language Act was passed to protect the rights of the linguistic minority in the Saami homelands.

Finnish-speaking Finno-Ugric tribes inhabited southern and western Finland by the early Middle Ages. Politically, Finland was part of Sweden from the 12th century until 1809. During this time, Swedish was the language of the nobility, officialdom, and education, with Finnish the spoken language of the majority. With annexation by Russia in 1809 and the publication of the epic *Kalevala* in 1835, Finnish nationalist sentiment grew, along with a drive for greater official equality between the two languages. Finland declared its independence from Russia in 1917. A 1922 language act provided the legal framework for equality between Finnish and Swedish, which remains more or less intact today. Finnish speakers currently make up 93.5% of the population, about 4.7 million people (Ethnologue 2000); another few hundred thousand speakers live in the diaspora, particularly in Europe, North America, and Australia. Finnish dialects include Savo, Southeastern, Häme, Southwestern, Ostrobothnian, and Finnish Lapland varieties. Finnish is an official language of the European Union.

Swedish-speaking settlers arrived centuries ago in the south and west but have always been in the minority in Finland. Currently Swedish speakers number about 300 000, roughly 6% of the population. They have a higher rate of bilingualism than Finnish speakers and their numbers have been in decline since the late 19th century. The semiautonomous Swedish-speaking Åland archipelago is an exception, and remains essentially monolingual. Swedish language programming makes up about 15% of television broadcasts in Finland; there is one national Swedish-language newspaper and one national radio station.

Other minority languages spoken include Kalo (or Kaale) Romani, the language of the 8–10 000 Romanies of Finland. Finnish Sign Language users number about 5000. Finno-Ugric minority languages spoken in Finland are Tornedalen Finnish (30 000 speakers, mainly along the Swedish border), Karelian (10 000), Estonian (6000), and a scattered population of Livvi (Olonets) speakers. Finland also hosts small populations of speakers of English, Russian, German, Romanian, Somali, Spanish, Tatar, Turkish, Vietnamese, Arabic, and Chinese speakers (Ethnologue 2000).

Finnish

F Karlsson, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Background

Finnish belongs to the (Baltic-)Finnic subbranch of the Finno-Ugric languages. The closest relatives are Karelian and Estonian. The Finno-Ugric and Samoyed languages form the Uralic language family.

In 2003, the number of Finnish speakers in Finland was 4.8 million, 92% of the population. Abroad, more than 1 million people speak Finnish (or are descendants of Finnish immigrants), especially in Sweden (300 000), the United States (600 000), Canada, and Australia. Finnish is one of the two national languages of Finland (the other is Swedish). Finnish obtained its position as national language in 1863 and ultimately 1902. Finnish has been used in writing since the appearance of the first parts of the Bible translation in the 1540s.

Phonology

Finnish has 8 vowel and 13 consonant phonemes, /i e æ y ø u o a/ and /p t k d s h v j l r m n ŋ/. /b g/ occur only in recent borrowings. /d/ is marginal because it occurs only as a product of morphophonological processes (consonant gradation).

Finnish stress is fixed on the first syllable. The quantity distinction is effectively phonemic. Both vowels and consonants can be phonemically short and long, and they combine with one another with few restrictions in both stressed and unstressed syllables, for example, *tuli* 'fire', *tuuli* 'wind', *tulli* 'customs', *tule* 'come!', *tulee* 'comes', *tuulee* '(the wind) blows'.

There are 16 diphthongs such as /ai æi ei oi ui ou æy ey ie uo yø/. The canonical structure of words is bisyllabic; the monosyllables can be counted in the tens.

Vowel harmony is a constraint on stems and suffixes. The vowels form three groups, the harmony vowels /y ö ä/ (front) and /u o a/ (back) plus the neutral vowels /i e/. The three vowel pairs from the harmony sets are often denoted by morphophonemic symbols /U, O, A/. Vowels from the front and back harmony sets cannot co-occur in native words whose vowels are drawn either from /i e ä y ö/ or /i e u o a/. Suffixes with harmony vowels have one front and one back variant occurring after front and back stems, respectively. Stems with neutral vowels count only as front. Thus (INE = inessive case):

talo-ssa
house-SING.INE
'in (a/the) house'

kylä-ssä
village-SING.INE
'in village'

venee-ssä
boat-SING.INE
'in boat'

Finnish orthography is often commended for being among the most efficient in the world, in the sense that it is almost perfectly phonemic. Each phoneme has its own unique letter, with the sole exception of /ŋ/ for which /ŋŋ/ is written <ng>. The phonemic perfection of Finnish orthography is true with respect to the careful normative pronunciation of the standard language. However, present-day colloquial Finnish has strayed from this ideal due to many contractions and elisions.

Morphology

Finnish is a suffixing language with an elaborate morphology. Nominals (nouns, adjectives, pronouns, and numerals) are inflected for number, case, and possessive. There are two numbers, fourteen cases, and five possessive morphemes, occurring as classes in this morphotactic order. Here are some examples of inflected Finnish nouns.

talo
house.SING.NOM
'house'

talo-t
house-PL.NOM
'houses'

talo-ssa
house-SING.INE
'in (a/the) house'

talo-i-sta-ni
house-PL-EL-POSS.1.SING
'out of my houses'

talo-o-nne
house-SING.ILL-POSS.2.PL
'into your house'

Finite verb forms are inflected for indefinite (called passive in traditional Finnish grammar), tense and mood (belonging to the same morphotactic position because tenses and moods are mutually exclusive), and person. There are two simple tenses, present and past, and two composite ones, perfect and pluperfect. There are four moods: indicative, conditional,

potential, and imperative. There are three grammatical persons in the singular and the plural, plus a fourth-person linking up with the indefinite.

sano-n
say-PRES.INDIC.1.SING
'I say'

sano-i-n
say-PAST-1.SING
'I said'

sano-isi-mme
say-COND.1.SING
'we would say'

sano
say.IMP.2.SING
'say!'

sano-kaa-mme
say-IMP-1.PL
'let us say!'

sano-ta-an
say-INDEF.PRES-4
'one says, people say'

Nonfinite verb forms (i.e., infinitives and participles) are inflected for indefinite, nonfiniteness, number, case, and possessive (INE = inessive case):

sano-a
say-INF.NOM
'to say' (infinitive I in traditional Finnish grammar)

sano-e-ssa-nne
say-INF-INE-POSS.2.PL
'when you are saying' (infinitive II)

sano-v-i-ssa
say-PRES.PART-PL-INE
'in the saying (ones)' (present participle)

sano-tta-e-ssa
say-INDEF-INF-INE
'when one says'

Almost every word form in Finnish, inflected or not, can be cliticized with an element from a set of five clitics with pragmatic functions. The most important one is the question morpheme /-kO/. For example:

talo-ssa-si-ko
house-SING.INE-POSS.2.SING-Q
'in your house?'

Finnish lexicography as manifested in *Nykysuomen sanakirja* (Dictionary of modern Finnish, 1951–1961) postulates 82 inflectional classes for nominals and 45 for verbs; at the other extreme, a generative description might operate with none but with a wealth of ordered (morpho)phonological rules. A surface-oriented morphological approach would recognize at least 10 nominal inflectional classes and six verbal ones.

Finnish word structure is characterized by considerable allomorphy both in stems and suffixes and therefore Finnish is not a typical agglutinative language. There are tens of more or less morphologically conditioned alternations. The most profound one is consonant gradation, which concerns both nominals and verbs. The long voiceless stops /pp, tt, kk/ are shortened to [p, t, k], and the short voiceless stops /p, t, k/ are weakened in various ways: /p/ → [m] (after /m/), /p/ → [v] (between vowels), /t/ → [d] (between vowels), /t/ → [l, r, n] (after an identical consonant), /k/ → [ŋ] (after /ŋ/), and /k/ → Ø (between vowels). These alternations are triggered by suffixation processes.

Syntax

Case marking has an important role in Finnish syntax in marking the arguments of the verb (nominative, genitive, partitive, accusative for grammatical subjects, objects, and predicate complements; and an assortment of local cases for adverbials). Due to extensive case marking, Finnish word order is free and used especially to indicate information structure, for example, subject-last for introducing new referents and leftward topicalization for linking to previous context. There are many highly productive nonfinite constructions. Premodifers in NPs agree with the head in number and gender; the finite verb agrees with the person and number of the grammatical subject.

Finnish as an Agglutinating Language

F Karlsson, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

A theoretically ideal agglutinative language would satisfy five criteria: there are no inflectional classes and all words of the same part of speech are inflected in the same way; there are several morphotactic positions for affixes of composite word forms, especially those of nouns and verbs; every morphological element (stem or affix) is clearly segmentable; the affixes convey one rather than several grammatical meanings; there are no morphophonological alternations in any element due to morphological processes such as affixation. As a corollary, every element has exactly one phonological shape (disregarding low-level phonetic processes) and no fusion of several meaning elements into one unsegmentable whole.

Morphotactic Structure

Finnish is a suffixing language with a 14-member case system. As for basic inflectional and cliticized morphotactic positions, the surface structures of Finnish nominal (nouns, adjectives, pronouns, and numerals), finite, and nonfinite verb forms are as follows (INE = inessive case, INS = instructive case, COND = conditional mood) (see Table 1, Table 2, and Table 3).

Inflectional Classes of Nominals

There is no consensus on how many inflectional classes there are for nominals and verbs. Traditional Finnish lexicography as manifested in *Nykysuomen sanakirja* (Dictionary of modern Finnish, 1951–1961) postulates 82 inflectional classes for nominals, whereas, at the other extreme, a generative description such as Wiik (1967) operates with none but a wealth of ordered (morpho)phonological rules. A surface-oriented morphological approach would recognize at least 10 nominal inflectional classes. The most important ones are those ending in B*i*, B*e*, and B*s* in the nominative singular. Four case forms (nominative, genitive, and partitive singular, partitive plural) unfold the allomorphic variation in the stems of each class, closely linked to the selection of particular ending allomorphs (NZ = nominalizer) (Table 4).

Class 1 is the largest and most productive one with the least amount of stem allomorphy, minimally only the stem vowel B*i* alternates with B*e* before the plural B*i*. At least 10 000 nominals are inflected according to class 1 and this is the pattern of most borrowings and other neologisms.

Classes 2 and 3 are closed: class 2 has some 220 words and class 3 around 40. Class 2 is more complex than class 1 as the stem vowel alternates also in the singular, and on top of that class 3 is more complex than class 2 by further eliding the stem vowel in SG.PART and also having alternations in the medial stem consonant. Many of the words in classes 2 and 3 are high-frequency words, for class 3, for example, *kuusi* '6,' *uusi* 'new,' *vesi* 'water,' *viisi* '5.'

For nominals in B*e*, class 5 is in principle closed (disregarding certain derivatives) even if it has more than 1000 members. Class 4 is small in contemporary Finnish, with less than 100 items, but this class is productive. Comparison of classes 1–3 and 4–5 discloses, not surprisingly, that the productive inflectional classes are those that have a minimal amount of stem allomorphy.

For nominals in B*s*, class 6 (>4000 items) is simpler and more productive than class 7 (some 800 items). Class 8 covers a common type of derivatives.

Inflectional Classes of Verbs

Nykysuomen sanakirja postulates 45 inflectional classes for verbs. A more generalizing approach would do with six classes, here presented by way of four central inflectional forms, the endingless (NOM) infinitive, the first person singular present tense indicative form, the third person singular past tense form, and the past tense participle in the nominative singular form (Table 5).

Table 1 Nominals

Stem	*Number*	*Case*	*Possessive*	*Clitic*
talo		ssa		
house		*INE*		
'in (a/the) house'				
talo		ssa	ni	kin
house		*INE*	*POSS.1.SG*	*also*
'also in my house'				
talo	i	sta	si	ko
house	*PL*	*EL*	*POSS.2.SG*	Q
'from your houses?'				

Table 2 Finite verb forms

Stem	*Indefinite*	*Tense/mood*	*Person*	*Clitic*
sano			n	
say			*PERS.1.SG*	
'I say'				
sano		i	t	ko
say		*PAST*	*PERS.2.SG*	*Q*
'did you say?'				
sano	tta	isi	in	pa
say	*INDEF*	*COND*	*PERS.4*	*even*
'even if one would say'				

Class 1 is by far the largest class with some 10 000 members. Around 2000 verbs belong to class 2, but this is presently the most productive verb class, obviously because overall there is less stem allomorphy in class 2 than in class 1; cf. especially the indefinite forms (called passives in traditional Finnish grammar) where the last morpheme is a personal ending for the indefinite 'fourth' person.

Class 4 is also a strong class with 4000 verbs. Class 3 has fewer than 20 monosyllabic verbs but around 1000 polysyllabic ones.

Morphophonological Alternations in Stems

As demonstrated by the example words of the nominal and verbal inflectional classes, Finnish word structure is characterized by considerable allomorphy, both in stems and suffixes, which detracts from the theoretical agglutinative ideal. Part of the allomorphy is most conveniently described in terms of item-and-arrangement morphophonological alternations, partly in terms of item-and-process directional rules.

Vowel harmony is an overriding constraint on stems and suffixes. The Finnish vowels form three groups, the harmony vowels /y ö ä/ (front) and /u o a/ (back) plus the neutral vowels /i e/. The three vowel pairs from the harmony sets are often denoted by morphophonemic symbols: U, O, A. Vowels from the front and back harmony sets cannot co-occur in native words whose vowels are drawn either from /i e ä y ö/ or /i e u o a/. Suffixes with harmony vowels have one front and one back variant occurring after front and back stems, respectively. Stems with neutral vowels only count as front. Thus:

talo-ssa
house-SG.INE
'in (a/the) house'
kylä-ssä
village-SG.INE
'in village'
venee-ssä
boat-SG.INE
'in boat'
auto-lla
car-SG.ADESS
'by car'
pyörä-llä
bike-SG.ADESS
'by bike'
veitse-llä
knife-SG.ADESS
'with knife'
tule-vat
come-PRES.INDIC.3.PL
'(they) come'
määrää-vät
decide-PRES.INDIC.3.PL
'(they) decide'
mene-vät
go-PRES.INDIC.3.PL
'(they) go'
anne-ta-an
give-INDEF-4
hala-ta-an
embrace-INDEF-4

Table 3 Nonfinite verb forms

Stem	*Indef*	*Nonfinite*	*Number*	*Case*	*Possessive*	*Clitic*
sano		a				
say		*INF*				
'to say'						
sano		a		kse	ni	
say		*INF*		*TRANSLV*	*POSS.1.SG*	
'in order for me to say'						
sano		e		ssa	si	ko
say		*INF*		*INE*	*POSS.2.SG*	*Q*
'when you are saying?'						
sano	tta	e		ssa		kin
say	*INDEF*	*INF*		*INE*		*also*
'also when one is saying'						
sano		va				
say		*PART.PRES*				
'saying'						
sano		nee	t			
say		*PART.PAST*	*PL*			
'said (pl.)'						
sano		v	i	en		
say		*PART.PRES*	*PL*	*GEN*		
'of the saying (ones)'						

Table 4 Inflectional classes of nouns

Class	*SG*	*SG.GEN*	*SG.PART*	*PL-PART*
(1)	lasi *glass*	lasi-n	lasi-a	lase-j-a
(2)	ovi *door*	ove-n	ove-a	ov-i-a
(3)	käsi *hand*	käde-n	kät-tä	käs-i-ä
(4)	nalle *bear*	nalle-n	nalle-a	nalle-j-a
(5)	vaje *lack*	vajee-n	vaje-tta	vaje-i-ta
(6)	varis *crow*	varikse-n	varis-ta	variks-i-a
(7)	vieras *guest*	vieraa-n	vieras-ta	viera-i-ta
(8)	rakka-us *love*-NZ	rakka-ude-n	rakka-ut-ta	rakka-uks-i-a

Vowel harmony is basically a phonological phenomenon. There are tens of other, more strongly morphologically conditioned alternations. The most profound one is consonant gradation, which concerns both nominals and verbs. Under complicated phonological and (partly opaque) morphological conditions, the long voiceless stops *pp*, *tt*, *kk* (which constitute two-phoneme combinations) are shortened to *p*, *t*, *k*, and the short voiceless stops *p*, *t*, *k* are weakened in various ways, e.g., *p* → *m* (after *m*), *p* → *v* (between vowels), *t* → *d* (between vowels), *t* → *l*, *r*, *n* (after an identical consonant), *k* → *ŋ* (after *ŋ*), *k* → zero (between vowels). The weak grade is triggered by suffixation processes, in particular the occurrence of a suffix closing the syllable in the beginning of which the strong grade occurs (Table 6).

However, the weak grade also occurs in many purely morphological contexts without suffixes closing the stem syllable, e.g., in certain imperative and indefinite verb forms and in the base forms (nominative singulars) of nouns belonging to inflectional class 5: *ker.ro* tell.IMP.2.SG, *ker.ro-.ta-an* tell-INDEF-4, *sa.de* rain.SG.NOM, *sa.tee-n* rain-SG.GEN.

About 20% of the Finnish vocabulary is subject to consonant gradation: 8000 nouns, 1000 adjectives, and 6000 verbs. Of the 1000 most frequent words, 30% participate in consonant gradation. This is a profound characteristic of Finnish.

Another set of typical morphophonological alternations are the vowel mutations in front of certain suffixes starting with B*i*. Long stem vowels are shortened, stem diphthongs are simplified, stem-final short B*i* changes to B*e*, stem-final short B*a* might change to B*o*, etc.:

maa
country.SG.NOM
ma-i-ssa
country-PL-INE
'in (the) countries'
tie
road.SG.NOM,
te-i-llä
road-PL-ADESS
'on (the) roads'
lasi
glass.SG.NOM
lase-i-ssa
glass-PL-INE
'in (the) glasses'
pila
joke.SG.NOM
pilo-i-ssa
joke-PL-INE
'in (the) jokes'

Many word forms simultaneously display several alternations, e.g., *virka* job.SG.NOM, *viro-i-ssa* job-PL-INE 'in (the) jobs' (gradation and mutation). The nominal inflectional class 3 is particularly complex. On top of gradation and mutation (deletion of B*e*) there is assibilation of stem-internal B*t*B in SG.NOM and deletion of B*e* also in SG.PART: *käsi* hand.SG.-NOM, *käte-en* hand-SG.ILL 'into (a/the) hand', *käde-llä* hand-SG.ADESS 'with (a/the) hand', *kät-tä* hand-SG.PART 'hand' (e.g., as direct object in negated clauses), *käs-i-ä* hand-PL-PART '(some indefinite) hands'.

Morphophonological Alternations in Suffixes

Suffixes might lose their final consonant in front of a consonant starting the next ending, or assimilate their first consonant to the last consonant of the preceding stem. Consonants are deleted in front of possessive suffixes: *maa-han* country-SG.ILL 'into (a/the) country', *maa-ha-mme* country-SG.ILL-POSS.1.PL 'into our country', *talo-n* house-SG.GEN, *talo-t* house-PL.NOM, *talo-mme* house-SG.NOM.POSS.1.PL ∼ *house*-SG.GEN.POSS.1.PL ∼ house-PL.NOM.POSS.1.PL. Note the three-way ambiguity arising due to consonant deletion in a form like *talo-mme* expressing nominative singular, genitive singular, and nominative plural.

The illative case has an extreme number of allomorphs. It has four basic suppletively related allomorphs, 'quasimorphemes,' occurring in different phonologically determined contexts: B*VVn*, B*hVVn*, B*seen*, B*siin*. The morphophoneme *V* is realized by reduplication as a copy of the preceding vowel. In

Table 5 Inflectional classes of verbs

Class	*INF.NOM*	*PRES.INDIC.1.SG*	*PAST.3.SG*	*PAST.PART.SG.NOM*
(1)	sano-a *say*	sano-n	sano-i	sano-nut
	anta-a *give*	anna-n	anto-i	anta-nut
(2)	hala-ta *embrace*	halaa-n	hala-si	halan-nut
	kara-ta *escape*	karkaa-n	karka-si	karan-nut
(3)	saa-da *get*	saa-n	sa-i	saa-nut
	haravoi-da *harvest*	haravoi-n	haravo-i	haravoi-nut
(4)	nous-ta *rise*	nouse-n	nous-i	nous-sut
(5)	lämme-tä *warm up*	lämpene-n	lämpen-i	lämmen-nyt

Table 6 Consonant gradation

kaup.pa	kau.pa-n	kau.pa-s.sa	*kauppa-a*
shop.SG.NOM	*shop-SG.GEN*	*shop-SG.INE*	*shop-SG.PART*
sil.ta	sil.la-n	sil.la-l.la	sil.ta-an
bridge.SG.NOM	*ridge-SG.GEN*	*ge-SG.ADESS*	*ge-SG.ILL*
ker.to-o	ker.ro-n	ker.ro-i-m.me	ker.to-.vat
tell-PRES.INDIC.3.SG	*tell-PRES.INDIC.1.SG*	*tell-PAST-1.PL*	*tell-PRES.INDIC.3.PL*

Syllable boundaries are indicated by periods.

addition, the final consonant may be deleted before possessives. Therefore the illative has no fewer than 36 allomorphs:

talo-on
house-SG.ILL
'into (a/the) house'
talo-o-mme
house-SG.ILL-POSS.1.PL
lasi-in
glass-SG.ILL
lasi-i-mme
glass-SG.ILL-POSS.1.PL
maa-han
country-SG.ILL
maa-ha-mme
country-SG.ILL-POSS.1.PL
puu-hun
tree-SG.ILL
puu-hu-mme
tree-SG.ILL-POSS.1.PL, etc.

Many suffixes have several allomorphs, each linked to specific stem selection criteria and/or inflectional classes. For example, the partitive allomorph B*ttA* only goes with nominal inflection class 5, B*tA* with classes 3, 6, 7, 8, and B*A* with classes 1, 2, and 4.

Fusion and Polyfunctional Suffixes

There are several polyfunctional suffixes where the grammatical functions cannot be segmented, e.g., B*t* (nominative plural), B*ten* (genitive plural, the segmentable genitive plural has the plural marker B*i*), B*ine* (comitative singular or plural), -*ttU* (indefinite fourth person perfect participle), B*kAA* (imperative 2.PL).

In colloquial Finnish, there is a tendency to drop B*i* in unstressed diphthongs. When this B*i* is the past tense marker, the mutated stem vowel becomes the only marker of the past tense function: *anta-a* give-PRES.INDIC.3.SG, *anto-i* give-PAST.3.SG, (colloquial) *anto* give-PAST.3.SG.

Conclusion

Karlsson (1983) distinguished 45 different morphophonological alternations. They create massive

allomorphy in both stems and endings. A two-way dependency exists between many stems and endings: certain stems take certain endings only, and certain endings go only with certain stems. This mutual boundedness implies that Finnish word forms are highly cohesive, a property that is amplified by vowel harmony stretching over the whole (uncompounded) word, and further amplified also by the fixed initial stress.

Thus, Finnish departs from the theoretically ideal agglutinative type in some respects, as regards the occurrence of nominal and verbal inflectional classes, allomorphy among the affixes, morphophonological alternations, endings expressing composite grammatical functions, and fusion of certain grammatical elements.

Finnish Lexicography

K Varantola, University of Tampere, Tampere, Finland

© 2006 Elsevier Ltd. All rights reserved.

Finnish lexicography can be discussed both as a language policy issue and as a commercial enterprise. The Research Institute for the Languages of Finland, KOTUS, is the national organization responsible for the languages spoken in Finland: Finnish, Swedish, and Saami. Five million people speak Finnish, 300 000 speak Swedish, and about 5000 speak Saami. Finnish belongs to the family of Finno-Ugric languages, of which Estonian is a closely related language and Hungarian, with about 15 million speakers, the biggest.

The dictionary projects undertaken by KOTUS can be described as academic projects of linguistic and cultural importance. Modern monolingual and bilingual dictionaries of Finnish naturally also have commercial value and are produced jointly with commercial partners. Recent achievements include the *Basic dictionary of the Finnish language* (BDFL) in three volumes (from 1994). The production and maintenance methods of this dictionary are traditional. Its predecessor, the comprehensive *Dictionary of modern Finnish*, was published in the years 1951–1961.

An updated version of the BDFL was converted in 1997 to an electronic format. This dictionary has about 100 000 entries. The latest electronic CD-ROM, Internet, and intranet edition of the BDFL was published in 2005 by Kielikone Oy, the major publisher of electronic dictionaries in Finland. No print updates are planned for the time being. Kielikone publications also include the electronic MOT dictionary library, which consists of a number of monolingual and bilingual dictionaries, with and without Finnish. The rights for the electronic versions have been purchased from various European print dictionary publishers.

The recent academically oriented products of KOTUS include the dictionaries of *Finnish dialects* (seven volumes, A to K, published), *Swedish dialects in Finland* (three volumes, A–K, published), *Old literary Finnish* (two volumes, A–K, published), and dictionaries of Karelian, Vogul (Mansi), and Cheremis (Mari). New dictionaries with more appeal to the general public include the *Finnish-Swedish general dictionary*, the *Basic dictionary of the Finnish Sign Language*, the *Finno-Swedish dictionary* (describing the Swedish spoken in Finland), and a Finnish-Estonian dictionary in two parts. This modern dictionary has more than 90 000 entry words and was compiled and published in 2003 in cooperation with the Institute of the Estonian Language in Tallinn.

Commercial lexicography in Finland is practiced in a challenging environment. Print dictionaries are expensive, because the potential market is small and basically restricted to Finnish-speaking audiences. Two major publishers, WSOY and Gummerus Oy, have accepted the challenge and produce a majority of the dictionaries on the market. WSOY has over the years published a number of large bilingual dictionaries between Finnish and English, Swedish, German, Spanish, and Russian. The update intervals tend to be long and vary from one language pair to another. In

allomorphy in both stems and endings. A two-way dependency exists between many stems and endings: certain stems take certain endings only, and certain endings go only with certain stems. This mutual boundedness implies that Finnish word forms are highly cohesive, a property that is amplified by vowel harmony stretching over the whole (uncompounded) word, and further amplified also by the fixed initial stress.

Thus, Finnish departs from the theoretically ideal agglutinative type in some respects, as regards the occurrence of nominal and verbal inflectional classes, allomorphy among the affixes, morphophonological alternations, endings expressing composite grammatical functions, and fusion of certain grammatical elements.

Commercial lexicography in Finland is practiced in a challenging environment. Print dictionaries are expensive, because the potential market is small and basically restricted to Finnish-speaking audiences. Two major publishers, WSOY and Gummerus Oy, have accepted the challenge and produce a majority of the dictionaries on the market. WSOY has over the years published a number of large bilingual dictionaries between Finnish and English, Swedish, German, Spanish, and Russian. The update intervals tend to be long and vary from one language pair to another. In

recent years, the demand has been highest for English and Swedish. Less expensive student and pocket versions are also available.

Gummerus has concentrated on the production of middle-range and smaller dictionaries. Its new English-Finnish dictionary (2005) has been compiled in the context of an EU-funded dictionary project, which has Finnish and British academic and commercial partners, and aims at a distinctly user-oriented approach in the dictionary entry structures.

Corpus lexicographical principles have so far been applied only sporadically in Finnish lexicography, usually in the context of international cooperation. However, extensive electronic text material in Finnish is publicly available for research purposes at the CSC, the Finnish IT Center for Science, governed by the Ministry of Education. The linguistic material is available as the Language Bank of Finland, an electronic text archive of Finnish and Finno-Swedish books, newspapers, and magazines. The archive consists of more than 200 million words. A 22-million-word Finnish subcorpus of newspaper texts (the 1995 issues of Helsingin Sanomat, the largest Finnish daily newspaper) has been analyzed with Kielikone's Textmorfo parser. The language bank now also includes a speech corpus – an annotated radio and TV corpus of approximately 17 hours of recordings in 2003 from the Finnish Broadcasting Company, YLE.

First Grammatical Treatise

M P Barnes, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

First grammatical treatise (*FGT*) is a modern title for a 12th-century text. In the Icelandic manuscript *Codex Wormianus* (AM 242 fol.), probably written about 1360, four treatises on native phonetics/phonology, orthography, style, and poetics are appended to a redaction of Snorri Sturluson's prose *Edda* (a textbook of Norse poetics). The *FGT*, which has no heading, is the oldest of these and precedes the others in the manuscript. Whether the scribe who compiled *Codex Wormianus* had access to the original text of the *Treatise* or was copying from a copy cannot be determined.

Chiefly on the basis of the Icelandic sound system described, but also because of the occurrence of certain archaic phonological and morphological forms and a rather rambling style associated with early attempts to write the vernacular, the *FGT* has been dated to the 12th century, and by some scholars to the narrower period 1120–1150. The identity of the author is unknown; as is where he wrote his work. His aim, which arose from dissatisfaction with existing scribal practices, was to create an orthography for Icelandic that would eradicate all ambiguity. His solution was to use a unique written character for each sound that could 'change the meaning' (*máli skipta*) of a word. The distinctive vowel sounds are established by the use of minimal pairs. By contrasting, for example, *sár* 'wound' with *sǫ́r* 'wounds,' the First Grammarian (FG), as the author is commonly known, shows that the sequence [sa:r] gives a different meaning from [sɔ:r], necessitating the use of two distinct vowel symbols if ambiguity is to be avoided. The vowel system arrived at contains 36 distinctions: 9 qualitatively different vowels, each of which can be either oral or nasal, long or short. Not all of these can in fact have been distinctive. The short nasals in

First Grammatical Treatise

M P Barnes, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

First grammatical treatise (*FGT*) is a modern title for a 12th-century text. In the Icelandic manuscript *Codex Wormianus* (AM 242 fol.), probably written about 1360, four treatises on native phonetics/phonology, orthography, style, and poetics are appended to a redaction of Snorri Sturluson's prose *Edda* (a textbook of Norse poetics). The *FGT*, which has no heading, is the oldest of these and precedes the others in the manuscript. Whether the scribe who compiled *Codex Wormianus* had access to the original text of the *Treatise* or was copying from a copy cannot be determined.

Chiefly on the basis of the Icelandic sound system described, but also because of the occurrence of certain archaic phonological and morphological forms and a rather rambling style associated with early attempts to write the vernacular, the *FGT* has been dated to the 12th century, and by some scholars to the narrower period 1120–1150. The identity of the author is unknown; as is where he wrote his work. His aim, which arose from dissatisfaction with existing scribal practices, was to create an orthography for Icelandic that would eradicate all ambiguity. His solution was to use a unique written character for each sound that could 'change the meaning' (*máli skipta*) of a word. The distinctive vowel sounds are established by the use of minimal pairs. By contrasting, for example, *sár* 'wound' with *sǫ́r* 'wounds,' the First Grammarian (FG), as the author is commonly known, shows that the sequence [sa:r] gives a different meaning from [sɔ:r], necessitating the use of two distinct vowel symbols if ambiguity is to be avoided. The vowel system arrived at contains 36 distinctions: 9 qualitatively different vowels, each of which can be either oral or nasal, long or short. Not all of these can in fact have been distinctive. The short nasals in

particular must be discounted since they are in each case preceded or followed by a nasal consonant. The FG's analysis of Icelandic consonants tells us something about their distribution, but his main aim is to show that for most of them length is distinctive, which he once again demonstrates with minimal pairs (e.g., *vinna* '[to] work' *v. vina* 'of friends [gen. pl.]'). Instead of gemination, he recommends the use of small capital letters to denote long consonants for the sake of speed and to save parchment. Allophonic variation is ignored: thus [θ] and [ð], for example, which are positional variants of /θ/, are both to be written 'þ.'

The *FGT* is a highly important work. Apart from giving us an account of the sound system of 12th-century Icelandic, it shows more clearly than other medieval treatises on language the problems involved in adapting the roman alphabet to a vernacular and offers a coherent and systematic solution. In addition, it provides insights into the pronunciation of Medieval Latin. The use of minimal pairs anticipates by some 800 years the main tool of phonemic analysis. The FG's description of Icelandic phonology tallies wherever it can be checked with the results of historical linguistics (each of the nine long nasal vowels identified, for example, can be shown at one time to have been followed by a nasal consonant). This, together with the conservatism of Icelandic, has led many scholars to posit a system much like the one the FG describes for Viking-Age Scandinavian in general. Important as the *FGT* seems to the modern linguist, it was clearly not highly prized in the author's day. It exists only in the copy made by the *Codex Wormianus* scribe, and there is no compelling evidence that any of the FG's recommendations were ever adopted.

The British linguist J. R. Firth (1890–1960) had an indisputable influence on the development of general linguistics in Britain both as an academic discipline and as a field of study. His influence until the 1960s within Britain is easily recognized (see, among others, Palmer, 1994; Brown and Law, 2002; Rebori, 2002). The assessment of his posthumous influence is nevertheless difficult.

Some key terms are valuable tools for a summary approach to the problem. Thus, 'London School of Linguistics,' 'Firthianism,' and 'Neo-Firthianism' convey the reference to sets of notions drawn from Firth's theories and shared by a group of linguists.

The term 'London School' was initially used by Firth in his *Papers in Linguistics 1934–1951* in two contexts: first, to refer to the tradition of studies in phonetics centered in London and led by Daniel Jones (1881–1967) (Firth, 1957: 110), and second to refer to the school of linguistics that was starting to develop during the 1930s at the School of Oriental and African Studies (SOAS) in London (Firth, 1957: 141, 145). Firth worked at SOAS from 1938 until his retirement in 1956.

From the 1940s onward SOAS radiated Firth's linguistic ideas and philosophy out to the rest of Britain. Firth's was the only indigenous theory of general linguistics at a moment when general linguistics was just preparing for its institutional birth in Britain (Robins, 1969). These historical facts together with Firth's well-known dominating personality allow the

particular must be discounted since they are in each case preceded or followed by a nasal consonant. The FG's analysis of Icelandic consonants tells us something about their distribution, but his main aim is to show that for most of them length is distinctive, which he once again demonstrates with minimal pairs (e.g., *vinna* '[to] work' *v. vina* 'of friends [gen. pl.]'). Instead of gemination, he recommends the use of small capital letters to denote long consonants for the sake of speed and to save parchment. Allophonic variation is ignored: thus [θ] and [ð], for example, which are positional variants of /θ/, are both to be written 'þ.'

The *FGT* is a highly important work. Apart from giving us an account of the sound system of 12th-century Icelandic, it shows more clearly than other medieval treatises on language the problems involved in adapting the roman alphabet to a vernacular and offers a coherent and systematic solution. In addition, it provides insights into the pronunciation of Medieval Latin. The use of minimal pairs anticipates by some 800 years the main tool of phonemic analysis. The FG's description of Icelandic phonology tallies wherever it can be checked with the results of historical linguistics (each of the nine long nasal vowels identified, for example, can be shown at one time to have been followed by a nasal consonant). This, together with the conservatism of Icelandic, has led many scholars to posit a system much like the one the FG describes for Viking-Age Scandinavian in general. Important as the *FGT* seems to the modern linguist, it was clearly not highly prized in the author's day. It exists only in the copy made by the *Codex Wormianus* scribe, and there is no compelling evidence that any of the FG's recommendations were ever adopted.

Firth and the London School

V Rebori, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The British linguist J. R. Firth (1890–1960) had an indisputable influence on the development of general linguistics in Britain both as an academic discipline and as a field of study. His influence until the 1960s within Britain is easily recognized (see, among others, Palmer, 1994; Brown and Law, 2002; Rebori, 2002). The assessment of his posthumous influence is nevertheless difficult.

Some key terms are valuable tools for a summary approach to the problem. Thus, 'London School of Linguistics,' 'Firthianism,' and 'Neo-Firthianism' convey the reference to sets of notions drawn from Firth's theories and shared by a group of linguists.

The term 'London School' was initially used by Firth in his *Papers in Linguistics 1934–1951* in two contexts: first, to refer to the tradition of studies in phonetics centered in London and led by Daniel Jones (1881–1967) (Firth, 1957: 110), and second to refer to the school of linguistics that was starting to develop during the 1930s at the School of Oriental and African Studies (SOAS) in London (Firth, 1957: 141, 145). Firth worked at SOAS from 1938 until his retirement in 1956.

From the 1940s onward SOAS radiated Firth's linguistic ideas and philosophy out to the rest of Britain. Firth's was the only indigenous theory of general linguistics at a moment when general linguistics was just preparing for its institutional birth in Britain (Robins, 1969). These historical facts together with Firth's well-known dominating personality allow the

conclusion that there was a school centered on him and located mainly at SOAS during his lifetime. The main topics developed by Firth and put into practice together with the London school were, briefly:

- importance of theory over procedures or methods;
- meaning stated at any linguistic level;
- context of situation;
- collocation;
- colligation;
- system and structure;
- restricted languages;
- prosodic analysis;
- renewal of connection.

The publication of *Studies in Linguistic Analysis* in 1957, a collection of papers by Firth and his pupils, is the last body of work written under his personal influence. It symbolizes the dividing line between the London school centered on him and 'Firthian' linguistics – the latter being the work inspired by Firth's ideas and carried out by the first generation of British linguists who now spread into the newly founded linguistics departments in Britain.

With Firth's death in 1960, a debate which continued into the 1970s took place (Langendoen, 1964; Langendoen, 1968; Monaghan, 1979). The parties to the debate were the 'Firthians' and the 'Neo-Firthians.' Although the use of labels to identify a body of work with any school or group was rejected, especially by the Neo-Firthians (Halliday, 1966), in the context of the debate both expressions refer to Firth's pupils, who were at the time divided according to their affinities either with the linguistics practiced by the members of the SOAS department previously headed by Firth (Firthians) or with the work done by and under the leadership of M A K Halliday (Neo-Firthians).

The main topics under debate were:

- the study of linguistic patterns with reference to how, when, and where;
- the independence of semantics from grammar;
- the existence of central language cores;
- the use of statistical procedures in lexical analysis;
- notions of 'restricted language' and 'register';
- change in form and change in register;
- monosystemic vs. polysystemic categorization;
- the phoneme concept.

(see Mitchell, 1975; Palmer, 1968).

The debate between the Firthians and the Neo-Firthians faded with the dispersion of its figures and the growth of other approaches in the British linguistics scene, which imprinted a more eclectic and international profile. But Firth's influence can still be traced in 21st-century linguistics, in prosodic phonology, corpus linguistics, pragmatics, sociolinguistics, and systemic functional grammar (see Butt, 2001).

Firth, John Rupert (1890–1960)

J Léon, Centre National de la Recherche Scientifique, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

John Rupert Firth is the founder of the London School and one of the leaders of 'systemic linguistics.' He was born on June 17, 1890, and graduated in history at Leeds University in 1911. After World War I, which took him to Afghanistan, Africa, and India, he was Professor of English in the University of the Punjab at Lahore. In 1928, he took up the post of Senior Lecturer of Phonetics at University College (under the phonetician Daniel Jones), and, in 1938, after 15 months in India where he worked on the Gujarati and Telugu languages, he became Senior Lecturer of Linguistics and Indian Phonetics under Lloyd James, whom he succeeded as head of the department in 1941. From 1944 until his retirement in 1956, he became the first occupant of the Chair of General Linguistics at the University of London and was very active to develop general linguistics and phonetics in Great Britain. In addition, being an orientalist, he contributed to the beginnings of language study in India.

As he was very busy in teaching and creating chairs of linguistics in British universities and because his flow of publications was interrupted by World War II, John Rupert Firth published no major theoretical books, and his descriptive works are often considered programmatic. He wrote only two short books, early in his career: *Speech* in 1930 and *The tongues of men* in 1937. His papers were collected in two volumes: he published the first one, *Papers in linguistics (1934–1951),* in 1957; the second one, *Selected papers of J. R. Firth (1952–1959),* was edited posthumously in 1968 by one of his pupils, F. R. Palmer.

Firth's attention was essentially focused on phonology, semantics, and history of linguistics, and his main contributions to linguistics are prosodic analysis in phonology, following the tradition of Henry Sweet and Daniel Jones, and the contextual theory of meaning inspired by Malinovsky's use of context of situation and by Wittgenstein's conception of word meaning. His view on meaning and his refusal to separate phonology and suprasegmentals, caused Firth to be radically opposed to American structuralists. He promoted a 'polysystemic' conception of language, in opposition to Saussurian structuralism. The task of the linguist describing a particular language is to distinguish the different component levels, phonetic, phonological, grammatical, lexical, and semantic. The meaning of an utterance is its acceptability at all levels. He particularly focused on the phonological and the lexical levels, and some of his main achievements are the notions of context of situation and meaning by collocation. His programmatic views have since been concretized by his pupils under the name of the London School of Linguistics; among the most prestigious are M. A. K Halliday and J. M. Sinclair, John Lyons, Randolph Quirk in lexicology and systemics, and R. H. Robins in history of linguistics. Firth's original conception of lexis and meaning by collocation is now reinvested in corpus linguistics.

Firthian Phonology

R Ogden, University of York, York, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Firthian Phonology, better known as (Firthian) Prosodic Analysis (FPA), is a technique of phonological analysis associated with J. R. Firth and his colleagues and students at the School of Oriental and African Studies (SOAS) at the University of London. The historical and theoretical background of FPA is well documented by Anderson (1985). What is known about FPA comes mostly from analyses published in the 1950s; major papers appear in Palmer (1970), the Philological Society's *Studies in Linguistic Analysis* (1957), and in collections of Firth's writings (Firth, 1957; Palmer, 1968), which contain work spanning Firth's career as a linguist.

FPA is not a very accessible linguistic theory because the Firthians wrote no clear, definitive statement of their linguistic thought, seeing their work as experimental and ongoing. They experimented freely with notation; their analyses (often of unfamiliar languages) tended not to be published in major international journals, were deliberately *ad hoc*, and did not make claims to universality. They published no major work on a European language (although they did conduct such work; see Ogden and Kelly, 2003). All these things contributed to FPA remaining a relatively parochial phenomenon, although many of its most radical ideas resurface in later phonological theories.

The influence of FPA runs deep in British linguistics, since many of the linguists employed in new linguistics departments in Britain in the 1960s were trained at SOAS. This means that another useful source of information on Prosodic Analysis is notes taken from the lectures of J. R. Firth, Eugénie Henderson, and Eileen Whitley, who developed a prosodic analysis of English but published very little. Significant collections of such unpublished material are held at SOAS and the University of York.

Important characteristics of FPA include the following: it is primarily a theory of representations (Anderson, 1985); it treats language as a complex set of interacting systems, each with its own characteristic properties (i.e., FPA is **polysystemic**); it foregrounds grammatical relations in establishing phonological systems; and it is rooted in phonetic analysis, yet it makes a strict separation between different types of linguistic information.

Main Concepts

In order to illustrate some of the main concepts of Prosodic Analysis, let us look at a piece of analysis by Eileen Whitley. The example is taken from notes on lectures she gave in the 1950s, and is based on Irish consonant mutation.

In the left-hand column of Table 1, the case and number of the noun is given. The center column contains a 'reading transcription': this is a systematic phonetic transcription that has no phonological status. Its function is to represent in a systematic way the 'phonic material.' For Firth, linguistic phonetics was a level of abstraction over individual occurrences of spoken material. The third column contains 'phonological formulae.' The formulae capture the analysis of the data into phonological units of two main types, 'prosodies' and 'phonematic units.' Note that this analysis, like most others in the canon of Prosodic Analysis, is partial: it handles a limited number of phonological patterns rather than providing a complete account of the phonological structure of Irish words.

Let us consider the construction of the analysis. Firstly, the material it is based on. In this case, a 'grammatical,' or morphological, paradigm (Determiner + Adjective + Noun) provides the framework for the analysis. This is a common starting point in much work in FPA. No one form of any of the lexical

(Whitley, unpublished manuscript.)

items is given primacy: neither the 'citation form' nor a particular grammatical case (such as an unmarked form) or number is chosen as the basic form from which others are derived. Instead, each grammatical form has associated with it a particular phonological form. In this sense, FPA is representational and not derivational, because it does not see some forms as derived from, or based on, others.

'Meaning' in its broadest sense has a central position in Firthian linguistics. By placing words in a grammatical frame like this, phonological variation which relates to morphological categories is foregrounded: this relates to what Firth called the 'major function' of phonological categories as conveying grammatical contrast, as opposed to the 'minor function' of conveying lexical contrast. Another effect of starting out with data this way is that the **syntagmatic** relations between items – that is, the ways in which units such as words and syllables are joined – are given prominence. This is a very different approach from that of the contemporaneous phonemic analysis, which was based on minimal pairs of contrasting lexical items. Robins (1957) comments that phonemic analysis, in contrast with FPA, highlights **paradigmatic** relations. In FPA, both syntagmatic and paradigmatic relations are important, but analysis starts from the syntagmatic ones.

The phonological formula contains essentially two kinds of unit, **prosodies** and **phonematic units**. Robins (1957) suggests there are two kinds of prosody: **demarcative** and **extensional**. Demarcative prosodies delimit particular structures. This means that properties that are a feature of a particular structure are handled as prosodies. Examples include glottal stops in German (German, Standard) V-initial words or laterals in Thai, which are limited to syllable onset position. Extensional prosodies capture phonological properties which hold over longer stretches of material, such as nasalization in Terêna, which marks third person singular. Henderson (1978, reported in Roberts, 1979) points out that this distinction is not made by Firth, but is an attempt to explain his thinking.

In the Irish example shown in Table 1, the small capital letters N, H, and P written in superscript represent phonological properties which belong to joins between words. In other words, word-initial plosivity in (1) ən k^{j}aun bjog and friction in (2) ən x^{j}iːŋ^{j} v^{j}ig^{j} are treated as prosodies of word-junction; and in the same examples, velarization ([un] and [og]) and palatalization ([iːŋ^{j}] and [ig^{j}]) at the word ends are treated as prosodies of the word-ending; these are notated as *w* and *y*, again written in superscript. Word-final *w* and *y* thus have characteristics of both extensional and demarcative prosodies.

It should be clear from the data that the word-junction prosodies {P H N} and the word-final prosodies {*w y*} have variable phonetic exponents (see below) according to the number, gender, and case of the grammatical piece. Thus, a link is established between morphology, lexis, and phonology. This analysis of data at **congruent levels** is one of the distinguishing features of FPA. Word-initial palatalization/velarization (*y w*) and aspiration (*h*) and its absence in this data have 'minor function' in that they are lexical properties, and not variable according to grammatical structure. These prosodies are written on the line.

Phonematic units are written in this analysis (as in most others) as capital letters that sit on the line. They are basic units of structure and are established on the basis of paradigmatic contrast: their closest equivalent in other theories is perhaps Trubetzkoy's underspecified 'archiphoneme' (Trubetzkoy, 1939). In this analysis, the phonematic units are not stated in full, but are left unspecified and general, as P and N, to stand for places in structure at which there are systems of contrast involving plosivity and nasality, respectively.

Two other concepts important in FPA should now be fairly clear. These are **system** and **structure**. Structure relates to syntagmatic relations, i.e., relations between units in a series. Syllables are one kind of structure; words are another. In Whitley's Irish analysis, πC—C$^{\pi}$ is a partial structure that describes nominal and adjectival lexical items, where π stands for a prosodic system. Another structure implicit in this analysis is the **piece**, a combination of words of a particular lexical class (here, Determiner, Noun, Adjective). A system is a restricted set of choices available at a given place in phonological structure: in the structure just described, the possible terms are {*w y h*} for the first π, {P} for the first C, {P N} for the second C, and {*w y*} for the second π. Note that the analysis is underspecified: for example, there are presumably more possible C-terms for the word endings.

Finally, the unit ə needs comment. In places where no system of contrast can be established for either vowels or consonants, FPA does not posit phonematic C or V terms, since these stand for phonematic units which are established on the basis of contrast. Thus, the smallest system contains two terms. A common device to handle this kind of case is the **syllabic**, such as ə to handle vowels whose quality is completely predictable. For consonants whose identity is

similarly syntagmatically or structurally predictable, a term written *c* or sometimes *r* ('reduplication') for consonants (e.g., Carnochan, 1957) is sometimes used rather than a capital letter such as *C*. Notice that nasality that is timed concurrent with or after syllabicity is written as a tilde, while syllable-initial nasality is written as *n* on the line.

Prosodic analysis is, distinctively, **polysystemic**. This means that one of its fundamental tenets is that at different places in structure, different phonological relations hold. Although *w* and *y* occur both word-finally and word-initially in this analysis, they are treated as different units because (1) they stand in different systems of contrast, with the possibility of *h* initially, but not finally, and (2) they have different functions, carrying lexical contrast initially, but handling morphological contrast finally.

A final aspect of FPA to observe is its separation of linguistic levels, especially phonetics and phonology. For the Firthians, phonology and phonetics describe different things and are different (but related) levels of abstraction with their own formal languages. Levels of linguistics statement are connected by statements of **exponency**. For instance, in the Irish example, the **exponents** of word-final *w* include velarization of the latter part of the syllable, while the exponents of word-final *y* include palatalization of the latter part of the syllable. Statements of exponency are sensitive to system and structure, so that the exponents of *y* and *w* in word-initial and final positions may be different. This is how FPA handles 'allophony' declaratively, without structure-changing or loss of information.

Prosodic Analysis and Modern Phonology

In 1970, a volume of collected papers was published (Palmer, 1970), an occasion that in some ways marks an ending of Prosodic Analysis. However, FPA has continued to be influential in a number of ways. There are obvious parallels between some of the ideas of FPA and autosegmental phonology (most notably the similarity between autosegmental 'spreading' and 'extensional' prosodies), although neo-Firthians have argued that these similarities are more superficial than real (Ogden and Local, 1994). More interestingly, the Firthian concepts of exponency, polysystemic analysis, and the insistence on phonological analysis as part of the wider social process of language have grown in influence, and have been incorporated into a variety of kinds of work. These are primarily centered around the significance of 'phonetic detail,' the constrainedness of FPA as a declarative theory, and a broad view of 'meaning' which goes beyond mere lexical meaning and takes serious account of context.

Some speech synthesis systems have formally modeled aspects of FPA. YorkTalk, IPOX, and ProSynth all use a combination of polysystemic analysis and phonetic exponency to model details of natural speech. Much recent work on the phonetic analysis of conversation draws on Firth's foregrounding of syntagmatic relations, and combines polysystemic linguistic analysis with a polysystemic sequential analysis. Finally, the Firthian insight that phonetic detail is sensitive to place in system and structure has been taken up in a theory of speech perception (e.g., Hawkins, 2003).

Fischer-Jørgensen, Eli (b. 1911)

F Gregersen, Frederiksberg, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Eli Fischer-Jørgensen was born February 11, 1911, in Nakskov, Denmark; she is a prominent Danish phonologist and phonetician.

Fischer-Jørgensen took a major in German and a minor in French at the University of Copenhagen in 1936. Her M.A. thesis on dialect geography and the understanding of sound change was published in 1934. As a postgraduate student, she studied phonology with Martinet and experimental phonetics with Fouché and Durand (1938) and later E. Zwirner (1939). From 1939 until her retirement in 1981, she was affiliated with the University of Copenhagen; in 1966, she became the first professor of phonetics. In 1968, she was also the first woman to be elected to the Royal Danish Academy of Sciences. Eli Fischer-Jørgensen holds honorary doctorates from the universities of Aarhus and Lund (1978), as well as Copenhagen (1993) and Bayreuth (2003).

Influenced by the somewhat older Louis Hjelmslev, she became an important figure in the Linguistic Circle of Copenhagen in its first fruitful years (1931–1956) when the Copenhageners hoped to found a new structural linguistics. Fischer-Jørgensen's role was that of the phonetician and she throughout stressed the importance of taking phonetic substance and phonetic results into consideration when forging a structural phonology. In particular, this was a critique of Hjelmslev's attempt to create a purely formal theory without reference to phonetic substance. Fischer-Jørgensen's most important papers from this period are 'Remarques sur les principes de l'analyse phonémique' (1949), 'On the definition of phoneme categories on a distributional basis' (1952), and the classic 'Form and substance in glossematics' (1966).

Whereas Eli Fischer-Jørgensen's career includes both theoretical and historical works and a wide-ranging experimental *oeuvre*, her experimental treatises are always theoretically informed and reflect her complete mastery of the research history of the subjects and her theoretical works constantly refer to experimental results. This is nowhere demonstrated more convincingly than in her majestic *Trends in phonological theory* (1995), a thorough and critical discussion of all the major theoretical schools of thought based on her first-hand knowledge of both the theories and their spokesmen. Her most important experimental treatise deals with the Danish stød, a slight glottal stop that is central to Danish phonology and phonetics, though it is not present in all dialects of Danish. At the age of 90, she published a book on stress in older Danish (2001).

Fischer-Jørgensen has been active for an unusually long period as a teacher and as the head of the Institute of Phonetics and has thus taught and supervised several generations of linguists and phoneticians. All of them have been influenced by her high standards and her searching spirit, never settling for an easy solution.

Dr. Fischer-Jørgensen has always been actively interested in politics. During the German occupation of Denmark (1940–1945), she worked as an assistant to Professor C. Høeg, who directed the secret gathering of intelligence information on Danes cooperating with the German occupation forces. Fischer-Jørgensen has published her memoirs from this period (2005). In the years after her retirement, she has intensified her painting and has taught Danish to refugees and other immigrants to Denmark, with particular emphasis on pronunciation.

with a 300 Hz fundamental frequency is produced by muscles contracting 300 times per second. The rate of muscle contraction is affected by temperature, so as the water temperature increases, the fundamental frequency of the call increases.

Midshipman (*Porichthys* spp.) spawn in rocky tide pools in the eastern Pacific. Their calls are somewhat unique among fishes in that these fish will produce continuous sounds that last for several minutes up to an hour. Like other toadfishes, the males guard a nesting area and produce tonal sounds to attract females. Their mating system is interesting in that an alternative reproductive strategy to establishing a territory and calling to attract females has been adopted by sneaker males. These males are smaller and similar in size to females, and their sonic musculature is not as well developed as that found in calling males. Their strategy is to sit by and wait for a spawning event to begin and then sneak in and release sperm during the spawning event.

Toadfishes are one of the few fishes in which acoustic interactions have been identified between neighboring males. In the midshipman, since males produce long calls, the sounds of adjacent males often overlap. This results in an acoustic beating phenomenon where the interference patterns produce beats at the difference frequency between the adjacent males. These beats are detectable by the fish and could be used by females to discriminate sounds from concurrently calling males. Whether this is intentional on the part of the fishes, or just a byproduct of individuals being located close to one another, is not known.

In the gulf toadfish (*Opsanus beta*), males will often produce a grunting call that overlaps with their neighbor's boatwhistle. This has been dubbed 'tagging' behavior and may be related to dominance hierarchies between males or may be involved in maintaining the timing of calling between individuals. This, along with the acoustic beats, is one of the few examples of acoustic interactions between fishes.

Damselfishes

Damselfishes (Family: Pomacentridae) are found commonly on coral reefs throughout the world. Males guard a territory in which they prepare a nest in which females lay eggs. To attract females, they produce a pulsed sound while performing a behavior known as the signal jump. They repeatedly perform this courtship ritual up to several hundred times a day. Studies of closely related species (*Stegastes* spp.) have shown that each species produces a unique sound and that they can discriminate conspecifics from heterospecifics. There is also evidence for individual recognition of these courtship sounds.

The calling rates of individual males are highly variable; they cycle through bouts of high calling rates interspersed with periods of low calling rates. Sound production in the domino damselfish (*D. albisella*) peaks at dawn, much like the dawn chorus of birds. The level of sound production is tightly linked to the timing of spawning, which is locally synchronized in this species. Thus, on the day before and the day of spawning, calling activity reaches its highest levels.

The dominant frequency of the sound is inversely proportional to male size, so larger males make lower frequency sounds (see **Figure 3**). In many fishes, females choose to mate with the largest males. In some damselfishes, such as the bicolor damselfish, it appears that females choose mates with the lower dominant frequency. In other damselfishes, it appears that females choose to mate more often with males that call more frequently. The pairing of sound production with a visual display is unique to the damselfishes. Since it has been argued that fishes may have difficulty localizing sound underwater, the pairing of the visual display with the acoustic signal may help females find the calling male. Because the male will defend the eggs from predators, it would be advantageous for a female to choose a mate with greater energy reserves. Though the energetic costs of sound production are not known, they are likely less than those of the swimming motion that accompanies sound production. This coupling of signals may create a more honest signal of a male's energy reserves.

Figure 3 Spectrogram of courtship sound produced by the domino damselfish, *Dascyllus albisella*. This sound consists of seven pulses that range in frequency from approximately 200 to 600 Hz.

Damselfishes also produce sounds in other behavioral contexts, such as aggression and mating. All of these sounds are pulsed and similar to the courtship sound, but they vary in the number of pulses and loudness. For example, sounds produced during spawning typically have fewer pulses than courtship sounds and are much quieter. Aggressive sounds are louder, have longer pulse durations, and a faster pulse rate than courtship sounds. Interestingly, domino damselfish typically produce a single-pulse 'pop' sound when directing aggression against other species, rather than the multiple-pulse aggressive sound. This popping sound has energy over a broader frequency band than the aggressive sound and may be more detectable by a broad range of fishes that may vary in their hearing sensitivity.

Croakers and Drums

Croakers and drums (Family: Sciaenidae) are named for the sounds that they produce. Males have drumming muscles located on the body wall that are used to drum the swimbladder. In some species, females also possess sonic musculature, but it is not known how they use sounds in communication. The size of the drumming muscle increases during the breeding season and then regresses after the breeding season. Unlike the toadfishes and damselfishes, croakers and drums join choruses of calling males where sound levels can become so loud that they are audible above water.

Like the damselfishes and toadfishes, each species has a unique sound, which varies in its spectral and temporal characteristics (Figure 4). Even though these sounds are very common in coastal waters throughout the world, very little is known about the behavioral importance of these sounds to females and their role in mate choice.

Figure 4 Silver perch and spotted seatrout sounds. Note that the silver perch sounds are higher in frequency (500–5000 Hz) and are repeated at a consistent pulse rate. Spotted seatrout sounds have most of their energy in the range 200–400 Hz.

These choruses tend to take place at dusk and at night (Figure 5). Because of this and the fact that the estuaries in which these species are found have limited visibility, little is known about the behavior that accompanies sound production and spawning. The chorusing of spotted seatrout has been referred to as lekking, because the aggregations occur at specific spawning locations, such as passes, where the fish might not otherwise be found. These fishes often attract feeding dolphins, and it has been hypothesized that dolphins may passively listen for sound- producing prey. Stomach contents data on bottlenose dolphins indicate that sound-producing fishes, including toadfish and croakers, constitute a major part of the prey base of dolphins in Florida.

Conclusions

Acoustic communication in fishes has been studied for over 50 years, but much remains to be learned. Fish sounds tend to be species-specific and stereotypical. In this sense, they are similar to the calls produced by insects and frogs. There appears to be little geographic variability within a species in the sounds they produce, except for indirect effects, such as the effect of temperature on the fundamental frequency of toadfish calls.

The diversity in life histories of fishes provides a strong base from which comparative studies of the evolution of acoustic communication can be performed. These three examples of sound production by toadfish, damselfish, and croakers show that fish vary greatly in the types of sounds they produce and in the temporal aspect of calling behavior. In species with fixed territories, such as the toadfish and damselfish, there are acoustic interactions between neighbors. In chorusing species, such as the croakers, it is not clear whether there are acoustic interactions between individuals. Future work with hydrophone arrays and advanced sonar systems will allow these questions to be answered.

It is important to remember that many different types of signals are often combined, such as sound production with a visual display, despite the fact that we often treat them separately. Future studies will examine the integration of these signals to more completely elucidate communication in fishes.

Figure 5 Composite spectrogram showing one night of a chorus of silver perch in Charlotte Harbor, Florida. Sounds were recorded 10 s every 10 min. Sand seatrout begin calling approximately 19:00 h. Silver perch chorusing begins somewhat abruptly at 21:00 h. Strong vertical bars are due to clipping in the recording system when sound levels exceeded 144 dB re: 1 μPa.

Fishman, Joshua A. (b. 1926)

A Pérez Pereiro, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Joshua Fishman is a pioneer in the field of sociolinguistics, particularly in minority languages. Born on July 18, 1926 in Philadelphia to a Yiddish-speaking family, Fishman was aware from a very early age of the difficulties involved in maintaining a language that is different from that of the majority, especially when, like with Yiddish, the future of that language is uncertain. His interest and passion for issues of multiculturalism began when he was a child studying history and collecting foreign stamps. He put this interest into practice from an early age, founding and writing for the Yiddish youth magazine *Yugntruf*. Today, he is an outspoken supporter of bilingual education and heritage language programs in the United States and abroad.

Fishman studied at the University of Pennsylvania, receiving his combined Bachelor's and Master's degrees in 1948. Originally studying to be a dentist like his father, he soon became a history major with a minor in Spanish, with plans for graduate study in New York. During his studies he established a friendship with Max Weinreich, the co-founder of the YIVO Institute for Jewish Research and one of the preeminent scholars of Yiddish at the time. In 1948, he entered Columbia University to study psychology on the advice of his mentor, completing his doctorate in 1953 with a dissertation on the attitudes of Jewish youth regarding mainstream America.

Fishman's training in psychology and quantitative analysis gave him a perspective quite different from that of most linguists at the time and a sense of the importance of experimental research in the field. Fishman quickly became interested in integrating his interest in language with the field of social psychology, and from 1955 to 1958 he taught social psychology at City College of New York, incorporating sociolinguistic materials. In 1958, Fishman returned to the University of Pennsylvania, this time as Associate Professor of Psychology and Human Relations, but he would leave in 1960 to become Professor of Psychology and Sociology at Yeshiva University in New York. There, he achieved the title of Distinguished University Research Professor in 1966 and Emeritus Professor in 1988.

The field of sociolinguistics has been profoundly influenced, and indeed, defined by Joshua Fishman's work. Not restricted to Yiddish, his works, such as *Language loyalty in the United States* and *bilingualism in the barrio*, concern other immigrant languages, particularly Spanish. In these and other works Fishman addressed the issue of language maintenance and shift from a multidisciplinary perspective, taking into account aspects of history, culture, political organization, and economics that are related to language practice. By expanding his research beyond the United States, Fishman was able to study cases of language loss and revival (both successful and unsuccessful) worldwide, enabling other scholars and language advocates to draw meaningful conclusions about the methods that might apply in their own communities. At a time when over half of the world's languages are threatened with extinction, Joshua Fishman's combination of passion and scholarship continues to empower and inspire those who would protect this piece of their heritage.

Fleuriot, Léon (1923–1987)

P-Y Lambert, The Sorbonne, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Born in Morlaix (Finistère) in 1923, Léon Fleuriot studied history at the Sorbonne and became an 'agrégé' teacher of history in 1950. Trained in the study of Celtic by Édouard Bachellery in the École Pratique des Hautes Études (Sorbonne, Paris), he began to gather the earliest evidence of the Breton language and, in 1958, he was admitted to the French National Research Foundation (CNRS) to write a thesis on this subject. This work was completed in 1963, and published in 1964. Soon after he received a professorship in Celtic Studies at Rennes University (1966) and later on succeeded É. Bachellery as Directeur d'Études in the École Pratique des Hautes Études. He was acting as director of the research team of Celtic Studies in the CNRS, and as chairman of the editorial committee of the CNRS journal *Etudes Celtiques*, until his sudden death, on March 15, 1987. His impassioned interest in the history of Breton was coupled with a great concern for the specific features of Breton culture: he never tried to sever his theoretical research from the general problems of modern Brittany and particularly from the problem of its language survival.

His scientific work developed along the lines traced years ago by Joseph Loth (*see* **Loth, Joseph (1847–1934)**): Old Breton and Gaulish were his two main interests. Eager to extend knowledge of Old Breton, Fleuriot had been scanning many manuscripts of the 9th century in his search for new glosses. His painstaking labor was rewarded with important discoveries, particularly the glosses on Bede's scientific works (ms. 477, Angers, Bibl. Municipale) and on Priscian's grammar. Fleuriot doubled the number of Old Breton glosses; he published this enlarged corpus in the form of a dictionary, probably under the influence of Loth's *Vocabulaire Vieux-Breton*. He was also asked to write a grammar of Old Breton.

His other interest was Gaulish and Continental Celtic. Convinced as he was of the similarity of Gaulish to ancient British (or Brittonic), he was prepared to recognize what the facts later proved to be right. In his general approach to ancient Celtic, Fleuriot revealed his profound knowledge of the older states of Brittonic, but he was also prone to rely on intuition, and to underestimate the importance of other Indo-European evidence. Thanks to his tenacity, however, it can be considered proven that among Continental Celtic languages, Gaulish was the nearest to the ancestor of Brittonic languages; this link helps to fill the gap between Continental Celtic and insular (medieval) Celtic.

Later works of Fleuriot were inspired by his passionate interest for the early history of Brittany. As a young man, he conducted archaeological explorations at the estuary of Rieux (at 'Coz-Yaudet,' Ploulec'h, dép. – Côtes-d'Armor). Reacting against the 'hyper-criticism' of Ferdinand Lot and others, the historian wanted to reconsider the evidence of some legendary sources, such as the histories written by 'Nennius' and Geoffrey of Monmouth. To realize this aim, he used what he himself called 'linguistic proof,' such as toponyms and anthroponyms. His book, *Les origines de la Bretagne*, however, did not meet with real success among historians.

Flores Languages

M Donohue, National University of Singapore, Singapore

© 2006 Elsevier Ltd. All rights reserved.

The Austronesian languages of Flores, in southern Indonesia, all belong to the Central Malayo-Polynesian grouping, and can be divided internally into three groups, roughly western, central, and eastern. There are 11 western languages, prominent among them Manggarai and Ngad'a, which are more closely related to Bima than to the languages of the rest of Flores. The three eastern languages, Sika, Lamaholot, and Lewotobi, are related to the languages of the Solor archipelago as far as Alor. The five central Flores languages, most prominently Ende and Li'o, are the most isolating and show a chaining relationship, with the southwestern languages changing incrementally into the northeastern varieties. The languages of Flores typically employ prenasalized and imploded/preglottalized consonants, sometimes in contrast to voiced stops. Most commonly, the languages have a five vowel system with epenthetic schwas separating illicit consonant clusters. Because these epenthetic vowels do not receive stress, the epenthesis results in apparent exceptions to the penultimate stress rule. In Palu'e ['lama] 'rice' appears to contrast in terms of stress placement with [lɐ'ma] 'tongue,' but the difference is better analysed as an underlying difference between /lama/ and /lma/.

The languages of Flores lack extensive verbal morphology to mark voice. This is part of the general isolating tendency, although the eastern languages have verbal agreement, and most languages show varying degrees of cliticization, which show degrees of development toward agreement and case marking. The eastern language Sika, for instance, shows a full set of agreement prefixes on verbs, whereas Palu'e in the center has only one proclitic, *ak* = '1sg.subj'. The recent grammaticalization of this clitic is attested in the inability of an independent pronoun to occur in the same clause as the clitic, and the optionality of the clitic: *Aku ka lama* 'I eat rice,' or *Ak=ka lama*, but not **Aku ak=ka lama*. There are no other subject clitics in Palu'e, but there are four genitive enclitics that are used in nominalized clause: *ka=gu lama* 'my eating of the rice.' The central and western languages show voice alternations. Manggarai shows an alternation in voice that is morphologically marked in word order and the choice of VP-final subject clitic. Palu'e has an active/passive alternation with only AVP and PAV word orders marking the difference, but a variety of morphosyntactic tests showing the changed status of the A and the P. Thus, the AVP sentence *Kita ka lama wa'a* 'We ate that rice,' contrasts with PAV in *Lama wa'a kita ka* 'That rice was eaten by us.' Tests for subject, such as modification by floating quantifiers, makes this unambiguous: the clause-final quantifier *teti'ón* 'all' in *Kita ka lama wa'a teti'ón* can only modify the subject: 'We all ate that rice,' whereas in *Lama wa'a kita ka teti'ón* can only be interpreted as 'We ate all of that rice.' Other tests support this analysis of the A in a PAV construction as oblique, and the P as subject.

Symbolism and metaphor are present in both ritual and everyday speech. This is licensed by an unusually large number of homophones, partly because of constrained phonotactic possibilities. For instance, in Palu'e the fortuitous coming-together of PAN *bənua > *nua* 'house' and *nuSa > *nua* 'island' is used to enforce the sense of belonging to their island home. Another factor is the extensive precategoriality of lexical roots, such as *kti*, which has the referential sense 'knife,' the predicative sense 'cut off,' and the modificational sense 'severed, loose.'

fMRI Studies of Language

Introduction

Functional neuroimaging has fundamentally changed the types of information that can be acquired about the relationships between neural structures and behavior, and this has been particularly important in the study of human language. Reviews of language/brain relationships are typically organized around hypothetical linguistic processes and the brain regions where they occur. From such a perspective, research questions might include the functional localization of processes related to discourse coherence, past tense affixation, phonology, pragmatics, production, prosody, reading, semantics, sentences, syntax, and words.

However, it is unlikely that the brain makes these distinctions as clearly as we linguists and psychologists do. In the current review, we turn this approach inside out, so to speak, and focus on the variety of different linguistic tasks that produce neuronal activity in a given location. This approach does not make assumptions about what is 'done' in an area and allows a picture to emerge of the mechanisms underlying language function throughout the brain, as opposed to trying strictly to localize it. From this point of view, we discuss not only traditional auditory linguistic perceptual tasks but also nontraditional but more ecologically valid tasks (e.g., audiovisual speech perception). Furthermore, we view language production and perception not as functionally separable processes but instead as lying on a continuum. Thus, tasks involved in language production are discussed with the understanding, as illustrated by work in the visual system (see, e.g., Jeannerod, 1997), that in order to understand the mechanisms of perception, we must simultaneously understand the mechanisms of production. Finally, we identify and describe a number of nonlinguistic tasks that produce reliable neuronal activity in some of the same regions that process linguistic material.

This approach serves to highlight new findings that have emerged from the neuroimaging literature. The emerging model differs somewhat from the standard view, that left Wernicke's area performs receptive functions and left Broca's area performs expressive functions (e.g., Geschwind, 1965b). Neuroimaging studies have demonstrated that in addition to these 'classical' areas, other more distributed bilateral brain areas play a role in language processing. It seems that each of the regions implicated in language processing plays a role in other, nonlinguistic processing as well, making it more likely that language emerged phylogenetically from existing processing mechanisms, rather than formed *de novo* to create a dedicated language mechanism in these 'classical areas.' Certainly understanding these mechanisms will help us understand language function. Finally, neuroimaging studies suggest that language processing is 'embodied'; aspects of processing both 'lower-level' speech sounds and 'higher-level' word meanings appear to involve brain areas that would be used both to perceive and to produce those sounds or meanings. As described, the intent is to illustrate these points by brain region. First, however, we

provide a brief overview of fMRI, as this is the principal method used in the surveyed studies (for a more detailed explanation of fMRI, see Cohen *et al.*, 1993). We do not, however, hesitate to draw on existing PET studies for historical reasons or for support.

fMRI: Basic Principles

Magnetic resonance imaging (MRI) is a noninvasive method of imaging the brain with high spatial resolution. fMRI is a way of using MRI to highlight regional differences in blood flow that occur during human cognitive or motor performance. fMRI requires neither injection of contrast agents nor radiation exposure, allows for fast and randomized 'single trial' stimulus presentation, and has comparatively high spatial resolution. This has led fMRI to become the image acquisition method of choice in establishing brain/behavior relationships in cognitive neuroscience, supplanting positron emission tomography (PET) for this purpose. Unfortunately, fMRI acquisition is very loud, requiring caution both in the care of research subjects (protecting hearing) and, important for the present review, in the design and interpretation of imaging studies involving auditory language (though 'silent' fMRI is possible, e.g., Engelien *et al.*, 2002). Another disadvantage of fMRI is a loss of signal in regions of the brain close to bone or air-filled sinuses, such as the medial temporal and orbitofrontal regions (see, e.g., Schacter and Wagner, 1999).

MRI works by altering the spins of protons aligned along the longitudinal axis of an imposed magnetic field. After application of a radiofrequency pulse to the brain, the proton spins are tipped away from the longitudinal axis. As the spins recover to their original state, they produce a measurable signal, which forms the basis of the MR image. Contrast between different tissue types (e.g., white matter, gray matter) can be achieved by exploiting the fact that the mechanism for the proton's recovery depends on its local tissue environment.

The most commonly used form of fMRI uses the blood oxygen level dependent (BOLD) contrast method (Ogawa *et al.*, 1992) and measures a molecule that is correlated with blood flow, and its changes during task performance. This in turn is a surrogate marker of neuronal activity. The temporal resolution of blood flow is slow: the vascular response begins about 2 seconds after the onset of neural activity, reaches a peak around 5–7 seconds, and declines for several seconds thereafter (Cohen, 1997). Despite this sluggishness, fMRI has been creatively adapted to the detection of stimuli as brief as 34 milliseconds (Savoy *et al.*, 1995). fMRI does not measure blood flow directly, as in PET, but rather measures relative changes in blood oxygenation. When neural activity occurs, blood flow in that area increases above the actual oxygen demand (Raichle, 1989), increasing the concentration of hemoglobin in that area. Although there is an increase in both oxygenated and deoxygenated hemoglobin, it is the increase in (paramagnetic) deoxyhemoglobin at the venous side of the capillary bed that results in the signal detected with fMRI.

Functional MRI requires a 'subtractive' task design. That is, the BOLD signals produced during one condition at each location in the brain must be compared with those during another condition at the same location. Those areas with a higher signal in one condition than another, thresholded by some statistical procedure, are usually referred to as 'activation.' Tasks of interest can be compared with a 'resting' baseline or with a simple perceptual control task or even with complex tasks that are tightly matched on psychological grounds. In the first case caution is required, as activation associated with 'rest' may be influenced by the participant's spontaneous thoughts or thoughts about the tasks given to them or by nonfocused attentional processes (Binder *et al.*, 1999; Raichle *et al.*, 2001). Regarding using another task as control (called a cognitive subtraction), caution is necessary, as very subtle differences in the tasks may result in activation that differs in intensity, spatial extent, and location (Jennings *et al.*, 1997; Raichle *et al.*, 1994). However, designs have emerged that are not as contingent on the assumption of pure insertion. These include a number of specialized design approaches, each with a suggestive name, such as 'cognitive conjunction' (i.e., determining the overlap among two or more tasks sharing a common processing component), 'common baseline' designs (i.e., comparing all tasks with one baseline), parametric designs (i.e., varying a level, e.g., frequency of word presentation, of a dimension, or of a task), and 'selective attention' designs (i.e., stimuli do not change between tasks; rather, participants are required to attend to different aspects of the stimuli, e.g., syntax or semantics).

During fMRI scanning, stimuli are presented either in 'blocks' or in a single-trial or event-related design. In a block design, participants perform multiple trials of a particular task repeatedly before performing another task. In event-related designs, stimuli are presented one at a time and randomly. Event-related designs have an advantage in that they are relatively resistant to habituation, boredom, expectation, and adoption of a fixed strategy.

We start our linguistic discussion with tasks that are associated with the activation of auditory cortex, an early step in the cerebral cortical processing of

1. Transverse temporal gyrus (buried) and sulcus

Dorsal Pathway (white numbers)

2. Angular gyrus
3. Pars opercularis of the inferior frontal gyrus
4. Planum temporale (buried)
5. Posterior superior temporal gyrus and sulcus
6. Premotor cortex (motor cortex in sulcus)
7. Supramarginal gyrus of the inferior parietal lobule

Ventral Pathway (black numbers)

8. Anterior superior temporal gyrus and sulcus
9. Middle temporal gyrus
10. Pars orbitalis of the inferior frontal gyrus
11. Pars triangularis of the inferior frontal gyrus
12. Planum polare (buried)

Figure 1 Key to regions discussed in the text. Regions with white numbers roughly correspond to the dorsal pathway, whereas regions with black numbers roughly correspond to the ventral pathway. 'Buried' indicates that regions are internal to the surface and are exaggerated on the image so that they can be more easily visualized.

spoken language. Figure 1 shows the location of this and other regions discussed below.

The Transverse Temporal Gyrus

The Transverse Temporal Gyrus (TTG), or Heschl's gyrus, is a large bump or bumps on the lower bank of the Sylvian (or lateral) fissure, the most posterior-medial half of which is primary auditory cortex (Liegeois-Chauvel *et al.*, 1991). Language competence is generally thought to develop from and rely upon auditory decoding of stimuli; thus, understanding the auditory bases of speech requires understanding the kinds of information processing that occur in the TTG.

fMRI studies have supported the view that the medial half of the TTG contains a tonotopic gradient in which more medial aspects process high frequency, while more lateral aspects process low-frequency sound information (Bilecen *et al.*, 1998; Wessinger *et al.*, 1997). In addition, some studies have shown that a more lateral aspect of the TTG has a mirroring tonotopic organization (Engelien *et al.*, 2002; Talavage *et al.*, 2000). Besides frequency information, the TTG is sensitive to the duration (Binder *et al.*, 1994; Jancke *et al.*, 1999; Engelien *et al.*, 2002) and intensity (Bilecen, 2002; Jancke *et al.*, 1998) of auditory stimuli.

These properties suggest that the TTG plays an important role in *early* processing related to speech understanding. That is, frequency discrimination is important in decoding phonetic differences, and certain phonetic boundaries are defined by durations of specific portions of vocalizations. Furthermore, sensitivity to prosodic information requires sensitivity to small differences in frequency and temporal duration.

However, the TTG is not simply at the bottom of a hierarchical language system. The TTG is subject to top-down influences of attention (Jancke *et al.*, 1998). Furthermore, activation of the TTG is subject to influence from other modalities: seeing moving faces producing speech without the accompanying auditory speech activates the lateral aspects of the TTG in normal hearing individuals (Calvert *et al.*, 1997; Calvert and Campbell, 2003) and in deaf individuals (MacSweeney *et al.*, 2002a). Furthermore, the TTG is activated by signed language in both populations (MacSweeney *et al.*, 2002b). In addition, speech production alters activity in the TTG (Houde *et al.*, 2002; Numminen *et al.*, 1999), and evidence from nonhuman primates has suggested that this consists of inhibitory responses preceding and excitatory responses following vocalization (Eliades and Wang, 2003).

These results bring into question the strict conceptualization of the TTG as a primary area. Rather, feedback to and plasticity at the level of the TTG are probably important components for shaping our auditory experience during language tasks. That is, language competence is not simply a process of decoding auditory stimuli, but rather, our auditory experience is shaped by attentional factors, other cues in the environment, and our own experience in producing speech sounds. It is important that processing in other brain areas (e.g., areas important in attention or face processing) can influence processing in TTG, since this accentuates the distributed nature of language function in the brain, as opposed to strictly modular and hierarchical conceptualizations.

Processing Pathways

Despite this general fact, processing occurs in a *somewhat* hierarchical manner in primate auditory cortices. These cortices are organized into a core with surrounding lateral belt areas (for review, see Kaas and Hackett, 2000; Rauschecker and Tian, 2000). The core in human (i.e., the TTG) has been shown to be sensitive to all types of sounds, while surrounding belt areas are sensitive primarily to complex sounds (Binder *et al.*, 2000; Hall *et al.*, 2002; Wessinger *et al.*, 2001), with speech (i.e., very complex sounds, like words and sentences) producing the greatest lateral spread of activation in superior temporal (ST) cortices *both* anterior and posterior to the TTG (Binder *et al.*, 2000).

Auditory processing in the monkey is thought to proceed in multiple functionally distinct pathways with a ventral (i.e., toward the bottom of the brain) pathway that is more sensitive to *What* (i.e., identification of auditory stimuli) and a dorsal (i.e., toward the top of the brain) pathway more sensitive to *Where* (i.e., localization of auditory stimuli, Rauschecker and Tian, 2000). This physiological distinction has been variously adopted with regard to the human brain based on neuroimaging results (e.g., see Belin and Zatorre, 2000; Hickok and Poeppel, 2000, 2004; Scott and Johnsrude, 2003; Wise *et al.*, 2001), with the suggestion that there is a ventral pathway involved in the transformation of sound into meaning and a dorsal pathway involved in the transformation of sound to motor-based representations (for a detailed explication, see Hickok and Poeppel, 2004). That is, as described in this article, the ventral pathway is involved in semantic aspects of language function – for example, understanding the meaning of words and sentences. In contrast, the dorsal pathway is more closely involved in motor aspects of language function, like auditory motion perception, speech production, verbal working memory, and/or phonology or segmentation. The dorsal pathway is thus related to the action perception–production continuum.

These two pathways have different reciprocal connectivity with frontal regions (Hackett *et al.*, 1999; Romanski *et al.*, 1999). Here we follow a simplified version of these pathways with the reality that there are probably many such pathways. First, we survey tasks that activate the ventral pathway. This pathway involves cortices anterior to the TTG connected, most likely via the uncinate fasciculus, to more anterior and ventral frontal cortices. Second, we examine tasks that activate the dorsal pathway, i.e., the cortices posterior to the TTG that are connected to more posterior frontal cortices, possibly via the arcuate fasciculus.

The Ventral Pathway: Temporal

The cortices of the ventral pathway in the temporal lobe are primarily in the ST regions anterior to the TTG and variously consist of the planum polare, the superior temporal gyrus (STG), and the upper bank of the superior temporal sulcus (STS). Also discussed are the temporal poles and the inferior and middle temporal gyri and the angular gyrus. As a general rule, the complexity of the stimuli that activate the anterior ST region increases as a function of the distance from the TTG: sounds, speech, words, sentences, and discourse produce increasingly anterior activity patterns respectively. This activity in the ventral pathway is unified functionally, in that it is associated mostly with semantic and grammatical aspects of language function.

Immediately anterior and lateral to TTG, bilateral ST cortices are active during tasks involving complex spectrotemporal structure, including both speech and nonspeech sounds (Belin *et al.*, 2000, 2002; Binder *et al.*, 2000; Davis and Johnsrude, 2003; Hall *et al.*, 2002; Scott *et al.*, 2000; Warren *et al.*, 2003). Intelligible speech seems to be confined to more anterior portions of the STG and especially the STS (with a leftward asymmetry, Scott *et al.*, 2000; Specht and Reul, 2003). Words tend to activate a more anterior extent of the ST region than sound alone (Mummery *et al.*, 1999; Specht and Reul, 2003) and connected speech, e.g., sentences, even more so (Friederici *et al.*, 2000a; Humphries *et al.*, 2001; Stowe *et al.*, 1998). Activation associated with discourse (i.e., relative to sentences) seems to extend into the temporal poles (Fletcher *et al.*, 1995; Robertson *et al.*, 2000; Tzourio *et al.*, 1998b). Collectively, it is these more anterior structures that are sensitive to semantic manipulations and grammatical structure (e.g., see Bavelier *et al.*, 1997; Chee *et al.*, 1999; Mazoyer *et al.*, 1993; Mummery *et al.*, 1999; Nobre *et al.*, 1994; St George *et al.*, 1999; Stowe *et al.*, 1998).

Whereas there is a small leftward asymmetry for intelligible stimuli, the right hemisphere is active for both intelligible and unintelligible stimuli, with a special preference for pitch variations and melodies (Belin *et al.*, 2002; Kotz *et al.*, 2003; Liebenthal *et al.*, 2003; Meyer *et al.*, 2002; Meyer *et al.*, 2004; Patterson *et al.*, 2002; Scott *et al.*, 2000; Specht and Reul, 2003; Zatorre, 2001; Zatorre *et al.*, 1992). For example, right anterior ST cortices have been shown to be more active while discriminating words based on emotional prosody than while performing a phoneme identification task (Buchanan *et al.*, 2000). Because of these hemispheric differences, it has been proposed that the left hemisphere is more involved in fine-grained temporal resolution, whereas

the right hemisphere is more involved in the frequency domain (Poeppel, 2003; Tallal *et al*., 1993; Zatorre *et al*., 2002).

In addition to anterior ST structures, posterior inferior STS has been implicated in the retrieval of words from memory based on semantic cues (Wise *et al*., 2001). Also, the middle temporal gyrus and angular gyrus (active in many of the cited studies) is thought to support semantic processing (Demonet *et al*., 1992; Vandenberghe *et al*., 1996). Similarly, reading words activates posterior middle temporal and anterior inferior temporal cortices in association with semantic aspects of processing (Fiez and Petersen, 1998; Hagoort *et al*., 1999; Herbster *et al*., 1997; Kuo *et al*., 2003; Price *et al*., 1997), and the medial and inferior temporal lobes are thought to support semantic verbal memory and retrieval (Bartha *et al*., 2003; Pihlajamaki *et al*., 2000).

In sum, activity in the ST region seems to course anteriorly as the complexity of stimuli increases from sound-based, intelligible speech, words, sentences, and discourse respectively. Furthermore, tasks yielding activity in the ST region and more inferior aspects of the temporal lobe are associated with semantic and grammatical aspects of language function. Together, those results support the contention that these aspects of the ventral pathway are involved in mapping sound-based representations to meaning (Hickok and Poeppel, 2004).

The Ventral Pathway: Frontal

Temporal lobe structures of the ventral pathway are connected via the uncinate fasciculus with more anterior and ventral aspects of the frontal lobe. These frontal structures include orbital, medial, and ventrolateral frontal cortices (cytoarchitectonic areas 10, 45, 46, 47/12). Neuroimaging studies have indicated that there are functional homologies between cortices of the temporal ventral pathway and these frontal areas. That is, the anterior aspects of the inferior frontal gyrus (IFG) – specifically the pars triangularis (cytoarchitectonic area 45) and pars orbitalis (cytoarchitectonic area 47/12) regions – are activated by tasks intended to assess higher-level linguistic processing related to semantic manipulations and grammatical structure.

These regions have been shown to be involved in strategic, controlled, or executive aspects of processing semantic information in words or sentences (Baumgaertner *et al*., 2002; Buckner *et al*., 1995; Dapretto and Bookheimer, 1999; Devlin *et al*., 2003; Fiez, 1997; Friederici *et al*., 2000b; Gabrieli *et al*., 1998; Gold and Buckner, 2002; Kapur *et al*., 1994; Petersen *et al*., 1989; Poldrack *et al*., 1999) and show reductions of activation during semantic priming (Demb *et al*., 1995; Wagner *et al*., 2000). These regions have also been reported to be involved in strategic, controlled, or executive aspects of processing syntactic information (Caplan *et al*., 1998, 2000; Embick *et al*., 2000; Fiebach *et al*., 2001; Inui *et al*., 1998; Just *et al*., 1996; Roder *et al*., 2002; Stromswold *et al*., 1996).

Activity in orbitofrontal regions and cytoarchitectonic areas 45 and 47, however, has been directly implicated in the perception and production of affective states, often regardless of the linguistic nature of the context (for a comprehensive review, see Phillips *et al*., 2003). It is no accident that areas of the brain implicated in emotional processing are also involved in semantic processes related to language, given that semantic qualities of words and sentences are imbued with affective qualities. Indeed, anterior and ventral frontal cortices are involved in processing emotional prosody in linguistic contexts (Buchanan *et al*., 2000; George *et al*., 1996; Kotz *et al*., 2003).

The Dorsal Pathway: Temporal–Parietal

The cortices of the dorsal pathway in the temporal lobe are primarily in the ST regions posterior to the TTG and variously consist of the planum temporale, the STG, the upper bank of the STS, and the supramarginal gyrus of the inferior parietal lobule. In various studies some combination of these regions is referred to as Wernicke's area.

As a general rule, the dorsal pathway is involved in mapping sound to motor-based representations (Hickok and Poeppel, 2004). Consistent with this view, as in the monkey, posterior ST cortices are involved in auditory motion perception in humans (Alain *et al*, 2001; Baumgart *et al*., 1999; Bushara *et al*., 1999; Pavani *et al*., 2002; Warren *et al*., 2002). This is an important aspect of language behavior (e.g., locating a friend based on his or her voice in a crowded room) and requires an orienting response with the head and/or body and thus a motor-based representation.

The dorsal pathway may also have a relationship with motor-based representations associated with the actual production of language. It has been stipulated that humans' ability to acquire and understand language requires a close connection between speech perception and stored speech sounds and motor areas involved in speech production (e.g., Liberman and Mattingly, 1985). Clearly, posterior ST and inferior parietal regions play a specific role in acoustic and phonological analyses and the storage and manipulation of speech stimuli (Belin *et al*., 1998, 2000; Benson *et al*., 2001; Binder *et al*., 1996, 1997, 2000; Burton

et al., 2000; Celsis *et al.*, 1999; Davachi *et al.*, 2001; Demonet *et al.*, 1992; Fiez *et al.*, 1995, 1996; Gelfand and Bookheimer, 2003; Hashimoto *et al.*, 2000; Hugdahl *et al.*, 2000; Jancke *et al.*, 2002; Jonides *et al.*, 1998; Kansaku *et al.*, 2000; Mazoyer *et al.*, 1993; Petersen *et al.*, 1988; Smith and Jonides, 1999; Tervaniemi *et al.*, 2000; Tzourio *et al.*, 1997, 1998a,b; Wise *et al.*, 2001; Zatorre *et al.*, 1992, 1996). Unlike anterior ST and inferior temporal cortices, which are also involved in acoustic and phonological analysis of stimuli, the posterior ST and inferior parietal cortices are involved in both overt and covert articulation, reading, and naming (Anderson *et al.*, 1999; Bookheimer *et al.*, 1995; Paus *et al.*, 1996; Price *et al.*, 1996; Wise *et al.*, 2001). That is, the perception of speech sounds overlaps the production of the same sounds in these regions (Buchsbaum *et al.*, 2001; Hickok *et al.*, 2000; Papathanassiou *et al.*, 2000).

The dorsal pathway is also involved in reading, another language task that may be tied to language production. fMRI studies have demonstrated a crucial role of the supramarginal gyrus in converting orthographic to phonologic encodings during reading. First, activity in this area is sensitive to the phonological demands of the reading tasks given to participants (Paulesu e*t al.*, 1993b; Price *et al.*, 1997). Second, studies have shown that the supramarginal gyrus is more active for reading relative to object naming (Moore and Price, 1999b) and for reading pseudowords relative to real words (Price, Wise, and Frackowiak, 1996; Rumsey *et al.*, 1997). This role of the supramarginal gyrus in converting orthography to phonology might relate to its anatomical location, facilitating interaction with frontal systems involved in motor output as would be required for reading (i.e., because of actual production requirements or the rehearsal aspects of verbal working memory; see Clark and Wagner, 2003; Davachi *et al.*, 2001; Jonides *et al.*, 1998a; Paulesu *et al.*, 1993). Indeed, it has been shown that the supramarginal gyrus is more active during overt relative to covert reading (Bookheimer *et al.*, 1995).

Posterior ST and inferior parietal regions, besides being involved in acoustic and phonological analysis and reading, are involved in other types of non-auditory-based linguistic processing. These regions are involved in the perception of sign language (Bavelier *et al.*, 1998; Braun *et al.*, 2001; Corina *et al.*, 1999; MacSweeney *et al.*, 2002b) and linguistically meaningful (and meaningless) facial movements (e.g., Campbell *et al.*, 2001) and are activated to a greater extent by many audiovisual language tasks that contain faces than auditory tasks alone (Jones and Callan, 2003; Mottonen *et al.*, 2002; Olson *et al.*, 2002; Wright *et al.*, 2003). Furthermore, the posterior ST regions are activated by the observation of nonlinguistic but biologically relevant movements and by implied movements of the eyes, mouth, and hands (for a review, see Allison *et al.*, 2000).

Thus, it seems that these posterior ST and inferior parietal regions are implicated not only in auditory aspects of perception and their coupling with motor output (as in auditory motion perception) but in all types of biological motion perception and their integration with other sensory modalities (e.g., see Calvert *et al.*, 2000; Sams *et al.*, 1991) and action performance.

The Dorsal Pathway: Frontal

Temporal lobe structures of the dorsal pathway are connected via the arcuate fasciculus with more posterior and ventral aspects of frontal cortices than the ventral pathway. These frontal structures include the pars opercularis of the inferior frontal gyrus (IFG; cytoarchitectonic area 44) and premotor cortex (cytoarchitectonic area 6). The latter structure connects directly to primary motor cortex (cytoarchitectonic area 4). Supporting the hypothesis that the dorsal pathway is involved in mapping between sensory- and action- or motor-based representations are the data that these areas are directly involved in the preparation for and the production of language (among other movements). Furthermore, like the temporal–parietal aspects of the dorsal pathway, posterior frontal cortices are involved in tasks intended to assess phonological processing.

Specifically, Broca's area of the IFG, comprised of the pars opercularis (roughly cytoarchitectonic area 44) and the pars triangularis (roughly cytoarchitectonic area 45), has long been viewed as supporting the mechanism by which auditory forms are coded into articulatory forms in service of language production (Geschwind, 1965). This characterization, however, is not completely accurate. Although Broca's area is activated during overt and covert articulation (Friederici *et al.*, 2000b; Grafton *et al.*, 1997; Huang *et al.*, 2001), this area is not itself involved in controlling articulation *per se* (Bookheimer *et al.*, 1995; Huang *et al.*, 2001; Papathanassiou *et al.*, 2000), but it may be a 'prearticulatory' region (Wise *et al.*, 1999). Indeed, other regions have been shown to be more consistently active than Broca's area during overt production (e.g., premotor cortices, Blank *et al.*, 2002; Wise *et al.*, 1999).

Further supporting the notion that Broca's area is not involved in controlling articulation *per se* is that activation in this area is not specific to oral speech. For example, Broca's area is activated during

production of American Sign Language (Corina *et al.*, 1999; Huang *et al.*, 2001) and is activated by the *observation* and imitation of nonlinguistic but meaningful goal-directed movements (Binkofski *et al.*, 2000; Ehrsson *et al.*, 2000; Grezes *et al.*, 1999; Hermsdorfer *et al.*, 2001; Iacoboni *et al.*, 1999; Koski *et al.*, 2002).

One suggestion regarding the function of Broca's area is that it is involved in tasks (both productive and perceptive, whether related to speech or not) that require segmentation (Burton *et al.*, 2000). Furthermore, tasks involving segmentation tend to activate more posterior aspects of Broca's area (i.e., the pars opercularis), whereas, as discussed in the section on frontal lobe characteristics of the ventral pathway, more anterior aspects of the IFG (i.e., the pars triangularis and orbitalis) tend to be activated by tasks that are semantic or grammatical in nature. One set of tasks requiring segmentation that consistently activates the pars opercularis are those intended to assess phonology (Buckner *et al.*, 2000; Burton *et al.*, 2000; Demonet *et al.*, 1992, 1994; Fiez *et al.*, 1995; Heim *et al.*, 2003; Muller *et al.*, 2001; Paulesu *et al.*, 1993a; Poldrack *et al.*, 1999; Zatorre *et al.*, 1992, 1996). Furthermore, tasks intended to assess verbal working memory – i.e., those thought to require active maintenance of phonological or segmental information (Baddeley and Logie, 1999) – also activate the pars opercularis of the IFG, in addition to premotor cortices (Awh *et al.*, 1995; Braver *et al.*, 1997; Cohen *et al.*, 1994, 1997; Jonides *et al.*, 1998; Paulesu *et al.*, 1993b; Schumacher *et al.*, 1996).

Premotor cortices are active when tasks require that a participant generate an articulatory/phonetic plan and are active to a greater extent than is Broca's area. In particular, studies of language production demonstrate (ventral) premotor and insula activity, but not necessarily IFG activity (Chao and Martin, 2000; Grabowski *et al.*, 1998; Grafton *et al.*, 1997; Heim *et al.*, 2002; Martin *et al.*, 1996; Riecker *et al.*, 2000; Wildgruber *et al.*, 1996, 2001; Wise *et al.*, 1999). In addition, speech perception overlaps speech production of the same speech sounds in premotor cortex (Wilson *et al.*, 2004). Furthermore, in contexts where a speaker's face is observable, audiovisual language comprehension activates the pars opercularis, premotor cortex, and primary motor cortex to an even greater extent than with auditory comprehension alone (Skipper *et al.*, 2002, 2004, 2005). The latter suggests that observable characteristics of facial movements might be understood and utilized in language comprehension through knowledge of how to produce the observed movements (Binkofski *et al.*, 2000; Kohler *et al.*, 2002; Rizzolatti and Arbib, 1998; Umilta *et al.*, 2001).

In sum, the tasks that activate frontal cortices of the dorsal pathway (i.e., speech production, verbal working memory, and perception of speech sounds) are functionally continuous with those that activate the temporal–parietal aspects of the dorsal pathway, though they are more closely associated with production. This supports the contention that this pathway subserves mapping between sensory- and motor-based representations (Hickok and Poeppel, 2004). Furthermore, it adds support to the hypothesis that under some conditions, language (or at least speech) is understood through the utilization of knowledge about speech production (e.g., Liberman and Mattingly, 1985).

There is, however, a very different manner in which these frontal cortices, especially premotor cortices, are involved in language understanding that does not fit with a clear dissociation between the dorsal and ventral pathways. Thus far, the distinction between the dorsal and ventral pathways has been that frontal areas associated with the dorsal pathway are involved in sensorimotor integration with regard to segmental aspects of speech perception/production, whereas the ventral route is involved in semantic operations. However, there is at least one way in which sensorimotor integration may play a role in semantic aspects of language processing, as suggested by lesion and neuroimaging studies of category effects in word processing. That is, temporal lobe lesions result in naming deficits for concrete entities, but not for actions, and prefrontal lesions show the opposite effect (Tranel, 2001; Tranel *et al.*, 1997a,b, 2003). Similar results have been found in non-brain-injured participants; this shows that tool naming selectively activates premotor regions relative to naming objects that are not manipulable (Chao and Martin, 2000; Grafton *et al.*, 1997; Martin *et al.*, 1996). Similarly, premotor cortex is more active during categorization of graspable objects (e.g., fruits, vegetables, and clothing) relative to animals and nonmanipulable man-made objects (Gerlach *et al.*, 2002).

Taken together, these results suggest that the semantic properties of words might encode features of their categories. Thus, the activation of tools might activate premotor regions because of the association between tools and reaching (Martin *et al.*, 1996). Indeed, some evidence suggests that action words (e.g., *run* vs. *type* vs. *smile*) activate motor cortices in a somatotopic manner (Pulvermuller *et al.*, 2000, 2001). Indeed, though the discussion at this point is centered on inferior frontal and premotor cortex, the principle that features of words are encoded or retrieved with word perception and production is a general one. For example, there is more processing

in visual areas for animals relative to tools (Martin *et al.*, 1996; Moore and Price, 1999a; Mummery *et al.*, 1998; Perani *et al.*, 1999), perhaps because we encode the latter more in terms of their visual properties and the former more in terms of their sensorimotor properties. It has been shown, for example, that color words activate visual areas involved in color processing (Martin *et al.*, 1995).

In summary, the dorsal pathway may encode action knowledge not only in relation to speech sounds (i.e., how to produce them) but also in relation to the semantic characteristics of word meaning (the word 'hammer' encodes knowledge about how to use a hammer). These two aspects of the action perception–production continuum with relation to language function are very different and probably rely on very different neural networks and probably represent an overlap between the dorsal and ventral pathways, as discussed here. This urges caution in strictly accepting the dorsal/ventral pathways distinction and suggests, rather, that such distinctions be utilized for heuristic purposes only, with the reality that things are much more complicated.

Occipital Cortices

Neglected thus far, among many brain structures, are occipital regions generally thought to support vision. Visual cortices clearly play an important role in the recognition of objects as an initial stage in object naming. The regions involved in processing object properties might also be involved in word processing (irrespective of the presence of an object) to the extent that words encode visual features as semantic content (e.g., color words activate visual areas involved in processing colors).

Of course, there is an entire system of visual language processing that overlaps with portions of the auditory language system but also includes a number of different pathways. Bilateral extrastriate cortex is likely involved in the early analysis of complex visual features associated with reading (Petersen *et al.*, 1990; Tagamets *et al.*, 2000). Aspects of the fusiform gyrus (i.e., the left ventral occipitotemporal sulcus) are especially responsive to written words (Cohen and Dehaene, 2004; Cohen *et al.*, 2000, 2002). Because of this, this region is often referred to as the 'visual word form area' and has been suggested to be somewhat modular and specialized, though it is more likely that this area in involved in other forms of (task-dependent) processing (Jobard *et al.*, 2003; Price and Devlin, 2003).

Interestingly, the hypothesis that action perception cannot be detached from action performance and vice versa seems to apply also to reading and writing. That is, writing modulates activity in the 'visual word retrieval system' (Nakamura *et al.*, 2002), and viewing letters activates premotor regions used in the act of writing (Longcamp *et al.*, 2003).

Conclusions

This review, rather than showing where specific kinds of linguistic processing occur (e.g., syntax), illustrates the various tasks that activate given regions. Brain activity resulting from these tasks show that 'classical' language areas are involved in language processing, but not necessarily in the ways originally prescribed, and that language processing in cortical areas extends beyond those originally thought to be involved in language function. Furthermore, the clear division of expressive and receptive functions is called into question with aspects of the perception of speech sounds and semantics involving a motor component. This review also highlights the functional similarities of connected regions loosely organized into distinct pathways. There seem to be pathways involved in sensory-meaning and sensorimotor translations related to language perception and production (Hickok and Poeppel, 2004). Such findings highlight the need to move away from strict localizationism (i.e., identifying brain regions responsible for a proposed cognitive function) and toward methods intended to discover the functional relationships between regions. Though such methods exist (e.g., McIntosh, 1999; McIntosh and Gonzalez-Lima, 1994) and have been applied to auditory (Gonzalez-Lima and McIntosh, 1994; McIntosh and Gonzalez-Lima, 1995), visual (McIntosh *et al.*, 1994), and motor tasks (Solodkin *et al.*, 2004), little work has been done to characterize the relationships among regions during language processing (Horwitz *et al.*, 1998; Krause *et al.*, 1999). Understanding these networks for language function clearly represents the next step of this exciting area of research.

Focus

J Miller, University of Auckland, Auckland, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

'Focus,' like many technical terms in linguistics, has various uses. Fortunately, they share a major property: They all have to do with highlighting constituents, making them stand out from the surrounding constituents in a clause or sentence. Speakers focus on constituents to highlight the information they carry, to contrast one piece of information with another, to introduce new information, to reintroduce information that has already been mentioned but dropped, to shift the listener's attention to another entity or topic of conversation, or to emphasize a piece of information. Focusing/highlighting cannot be examined in isolation; linguistic properties are interconnected and focusing has its converse, defocusing or making constituents less prominent, usually because they convey information that is treated by the speaker as familiar to the listener(s).

Different Concepts of Focus

Halliday

Halliday (1967) provided the first systematic discussion of focus. His account was very apt because it dealt with the use of pitch and stress to signal focus. Halliday posited information units that are realized as tone groups. A tone group contains one obligatory component, namely a segment carrying stress (a tonic segment), which may be a whole word or part of a word; it contains at least one optional component, the pretonic segment. One information unit is realized as one tone group, and the number and size of the information units in a given utterance reflect how the speaker has divided the message into blocks of information. Within each information unit the speaker selects a certain element or elements as points of prominence within the message. For example, (1) can be realized as (2a) or (2b), where the double obliques indicate tone group boundaries and capitals indicate the position of the tonic segment. (Current literature refers to the focal segment, which carries the focal accent.)

(1) John visited Susan yesterday

(2a) John visited SUSAN yesterday
(2b) JOHN visited Susan yesterday

The constituent carrying the focal accent is flagged as carrying information that the speaker treats as new – that is, as not available to the listener either by inference or because it has already been mentioned. Halliday emphasizes that 'new' means 'what the speaker chooses to present as new.' New information may simply be added to the available information or may contrast with it. (See Halliday, 1987: 277.)

(2a) is appropriate as a response to the question, 'Who did John visit yesterday?' whereas (2b) is a possible response to 'Who visited Susan yesterday?' To put it another way, the speaker who utters (2a) presupposes that John visited someone and specifies the someone. The speaker who utters (2b) presupposes that someone visited Susan and specifies that someone. As Lambrecht (1994: 210) stated, the information conveyed by (2b) is that "the person who visited Susan yesterday is John." The constituent carrying the focal accent provides a value for *x* in the proposition *x visited Susan yesterday.*

Contrastiveness: Chafe, Lambrecht, and Dik

Chafe (1976) asked what contrastiveness is. With respect to the example, *Ronald made the hamburgers*, Chafe spells out the factors involved: (1) background knowledge that a set of hamburgers was prepared, (2) a set of possible candidates for the cook, and (3) assertion of which candidate is the correct one. Contrastiveness is manifested principally by the placement of higher pitch and stronger stress on the focus of contrast, although IT clefts are an alternative device. Like Halliday, Chafe regarded the pitch phenomena as of primary importance and the use of syntactic constructions as secondary, but

'Focus,' like many technical terms in linguistics, has various uses. Fortunately, they share a major property: They all have to do with highlighting constituents, making them stand out from the surrounding constituents in a clause or sentence. Speakers focus on constituents to highlight the information they carry, to contrast one piece of information with another, to introduce new information, to reintroduce information that has already been mentioned but dropped, to shift the listener's attention to another entity or topic of conversation, or to emphasize a piece of information. Focusing/highlighting cannot be examined in isolation; linguistic properties are interconnected and focusing has its converse, defocusing or making constituents less prominent, usually because they convey information that is treated by the speaker as familiar to the listener(s).

Different Concepts of Focus

Halliday

Halliday (1967) provided the first systematic discussion of focus. His account was very apt because it dealt with the use of pitch and stress to signal focus. Halliday posited information units that are realized as tone groups. A tone group contains one obligatory component, namely a segment carrying stress (a tonic segment), which may be a whole word or part of a word; it contains at least one optional component, the pretonic segment. One information unit is realized as one tone group, and the number and size of the information units in a given utterance reflect how the speaker has divided the message into blocks of information. Within each information unit the speaker selects a certain element or elements as points of prominence within the message. For example, (1) can be realized as (2a) or (2b), where the double obliques indicate tone group boundaries and capitals indicate the position of the tonic segment. (Current literature refers to the focal segment, which carries the focal accent.)

(1) John visited Susan yesterday

(2a) John visited SUSAN yesterday
(2b) JOHN visited Susan yesterday

The constituent carrying the focal accent is flagged as carrying information that the speaker treats as new – that is, as not available to the listener either by inference or because it has already been mentioned. Halliday emphasizes that 'new' means 'what the speaker chooses to present as new.' New information may simply be added to the available information or may contrast with it. (See Halliday, 1987: 277.)

(2a) is appropriate as a response to the question, 'Who did John visit yesterday?' whereas (2b) is a possible response to 'Who visited Susan yesterday?' To put it another way, the speaker who utters (2a) presupposes that John visited someone and specifies the someone. The speaker who utters (2b) presupposes that someone visited Susan and specifies that someone. As Lambrecht (1994: 210) stated, the information conveyed by (2b) is that "the person who visited Susan yesterday is John." The constituent carrying the focal accent provides a value for *x* in the proposition *x visited Susan yesterday.*

Contrastiveness: Chafe, Lambrecht, and Dik

Chafe (1976) asked what contrastiveness is. With respect to the example, *Ronald made the hamburgers*, Chafe spells out the factors involved: (1) background knowledge that a set of hamburgers was prepared, (2) a set of possible candidates for the cook, and (3) assertion of which candidate is the correct one. Contrastiveness is manifested principally by the placement of higher pitch and stronger stress on the focus of contrast, although IT clefts are an alternative device. Like Halliday, Chafe regarded the pitch phenomena as of primary importance and the use of syntactic constructions as secondary, but

unlike Halliday he limited focus to contrast. Halliday regarded contrastiveness as only one property of focus – focused, new information can be cumulative to existing information or in contrast with it.

Lambrecht (1994: 290) proposed that the placement of focal accent is not to be explained in terms of contrastiveness. He treated contrastiveness as a gradient property that may be zero in a given context and related it to the inferences drawn by listeners in particular conversational contexts. With respect to *Who made the hamburgers*, he proposed that no limited set of candidates is implied.

Dik (1980: 210–229) classified different types of focus. He drew a distinction between shared and nonshared, or new, information; as in Halliday's account, it is the speaker who decides the status of a piece of information. Like Halliday, Dik treated focus as usually marking information as nonshared. Nonshared information is made salient, either by intonation or by constituent order or by focus markers such as particles and special focus constructions, or indeed by a combination. Dik provided a hierarchy of different types of focus; the examples are from Mackenzie and Keizer (1990). All the examples have in common that the speaker uses the focal accent to make information salient, presenting it as unshared or new.

Examples of the different types of focus are given in (3). Obviously, the placement of the focal accent is relevant only to speech. Spoken and written language share the syntax of the different types of focus, but in speech the syntax might well be reduced; for instance, in (3c) a possible spoken retort is simply *coffee*, with the appropriate pitch pattern and an appropriate voice quality.

(3a) Completive focus
Where is John going?
He's going to the market / to the market

(3b) Parallel focus
John and Bill came to see me. John was nice but Bill was boring

(3c) Replacing focus
John bought rice
No, he bought coffee

(3d) Restricting focus
John bought coffee and rice
No, he only bought coffee

(3e) Expanding focus
John bought coffee
Yes, but he also bought rice

(3f) Selecting focus
Would you like coffee or tea?
Coffee, please

Dik took Halliday's distinction between cumulative and contrastive focus, drew out the various reasons why a speaker might wish to highlight a constituent, and extended the range of devices to be recognized as highlighting. That is, the general concept of contrastive focus is all very well, but spontaneous spoken discourse yields a range of subtypes, some of which can be signaled in more than one way. For example, in addition to the responses given previously, (3c) can be responded to by *it was coffee* or *it was coffee he bought*.

Vallduví: Heads and Tails

Vallduví (1994) incorporated focus-as-new into an explicit information-handling model. Consider (4).

(4a) What did Sally give Andrew for his birthday?
(4b) She gave him a CD of Jean-Michel Jarre

Sentences encode a logico-semantic proposition and an information-packaging instruction. The proposition in (4) is GIVE (SALLY, SOMETHING, ANDREW). The information-packaging instruction indicates what part of a given sentence carries information and where and how that information fits into the hearer's information store. (Strictly speaking, it indicates where and how the speaker thinks the information fits in.) In (4b), the sequence *She gave him* is taken to be the ground, that which is already established in the speaker's information model. The 'established' entities are Sally and Andrew, and for both of these file cards have been opened. *A CD of Jean-Michel Jarre* is the focus, that is, information to be added to the hearer's information model by adding information to a file card – here the card for the entity given to Andrew. If necessary, the hearer opens a new file card.

The ground consists of a link element and a tail element. The link points to a specific file card in the hearer's knowledge store; in (4b) *she* and *him* point to the cards for Sally and Andrew. Link elements are typically pronominal and in speech carry low pitch and amplitude. In spoken English, the answer to (4a) would typically be *a CD of Jean-Michel Jarre*, with a zero link element. Tail elements are ground elements that are not links.

Transitions

The core concept of contrastive focus as employed by Halliday and Chafe turns out to have much in common with the concept of focus as used by Dik, and even with two apparently very different concepts – that of Grosz and Sidner (1990), which has to do with referential status, and that of Vallduví (1994), which has to do with the transmission of information. In order to accommodate the various concepts in one framework, we add the notion of communicative goal as deployed by Levy (1979) and bring in the further

concepts of macrofocus, relating to high-level, major transitions in a text, and microfocus, relating to low-level, minor transitions. The important notion here is 'transition,' which is also at the heart of Grosz and Sidner's work.

The concept of focus is invoked in accounts of how a given speaker and listener shift attention from one entity to another in a given context, thereby shifting the reference of pronouns, as described in the classic paper on centering by Grosz (1981) and in Grosz and Sidner (1990). The latter paper appeals not just to linguistic structure but also to the notions of intentional and attentional structure. The former has to do with the intentions of the speaker in producing a particular discourse or discourse segment and the latter with the salience of entities, properties, relations, and discourse purposes and intentions. We are concerned here with attentional structure since it, like focus, has to do with salience.

The important concepts are focus space and transition rule. A focus space is associated with each discourse segment and in it are representations of entities salient in that discourse segment – that is, entities that are mentioned explicitly or become salient as speaker and hearer work to produce and interpret utterances. Within focus spaces all Dik's different types of focus are relevant, as are the devices for introducing new entities and new propositions into focus spaces. Of course, speakers can choose one of these devices or simply use a neutral syntactic construction, as in much of the dialogue analyzed by Grosz and Sidner.

As a discourse is built up, speakers pass from one focus space to another and it is here that the concept of transition rule becomes relevant; speakers and writers may choose to make a given transition salient, and the text schema in (5), taken from Levy (1979), shows how they can do this.

(5) A text schema
(5a) I had a lousy day at work
(5b) i. Monday is a horrid day anyway.
ii. When I arrived . . .
iii. At the second year lecture . . .
iv. Right in the middle of my afternoon nap . . .
v. Just as I was leaving . . .
(5c) i. At the second year lecture
ii. the first thing was that the overhead projector was playing up
iii. then the students hadn't done any reading
(5d) iv. but what bugged me most was . . .

Essentially a time or place phrase is put into first position in a clause and these phrases connect and contrast with the previous text. (The phrases in first position in clauses are known as themes; in (5), *I*, *Monday*, *When*, *At the second year lecture*, *Right in the middle of my afternoon nap* are themes.) The text schema in (5) shows that there are major and minor transitions; the transition from the previous topic of conversation to the lousy day at work is very large and (5bi) could be preceded by *Can I tell you about my day? Talking about having a bad day*, *I'm glad someone had a good day*, and so on. The transition from topic set (5b) to topic set (5c) is less important, and the transitions within sets (5b) and (5c) are relatively minor. Nonetheless, they are signaled by the time progression from event to event conveyed by the theme phrases listed previously.

Transitions in texts are beyond the scope of this article but are relevant for typology. Transitions in a spontaneous Russian text are discussed in detail in Miller and Weinert (1998: 203–209); they invoked the concept of macrofocus for the major transitions and microfocus for the minor transitions. The transitions involve contrast but also cohesion, and they are rendered salient by various syntactic and lexical devices, such as *moreover*, *in addition*, *conversely*, *We turn now to a different but related topic*, and so on.

Focus Particles

The final use of focus has to do with words such as *even*, *only*, and *just*. These words are called 'discourse markers' or 'discourse particles.' They contribute to the complete interpretation of utterances: *Even Angus has heard of Bach* has the interpretation 'Contrary to your expectations (given what you know about Angus), Angus has heard of Bach'; *The dog only chewed the table this time* has the interpretation 'This time the dog chewed the table and nothing else' and invites the inference 'on some other occasion the dog chewed a lot more'; *Just open the window a bit* has the interpretation 'Open the window, but not very much, and I'm asking you politely.' In addition, *even*, *only*, and *just* give salience to *open a bit*, *the table*, and *Angus*.

All the uses of the term focus mentioned previously have to do with making constituents salient, but for different reasons: because they carry new information, because they signal a change of attention, because they signal a transition in a text (conversation, narrative, or serious discussion), or because the salience helps to signal some other important meaning, such as attitude.

Focal Accent and Syntactic Structure

New information has to do with whole propositions (and the clauses that convey them), predicates (as conveyed by verbs), or arguments of predicates

(as conveyed by noun or prepositional phrases). Lambrecht (1994: 223–228) demonstrated that the introduction of these different types of new information correlates with different syntactic structures and with the focal accent falling in different places. Where a whole proposition is new, the focal accent in English falls on the subject noun phrase (with an intransitive verb, at least); where a predicate is new, the focal accent falls on the verb and the subject noun phrase is typically a pronoun. Consider (6a), which is a possible answer to the question *What happened?* and compare it with (6b), a possible answer to the question *What happened to your car?*

(6a) Sentence focus (whole propositions)
My CAR broke down
(6b) Predicate focus
It broke DOWN
(6c) Argument focus
My CAR broke down

Where the whole proposition is new, the focal accent falls on *car*, but also where *car* is the argument that is new. Where the question being answered is *What happened to your car?* the focal accent is on *down* and the subject noun phrase is *it* since speakers do not repeat full noun phrases such as *your car* but use pronouns to refer to entities that have just been mentioned.

Corresponding to (6a)–(6c), French has three different structures, as in (7a)–(7c).

(7a) Sentence focus

J'ai	ma	VOITURE	qui
I have	*my*	*car*	*which*
est	en	PANNE	
is	*in*	*breakdown*	

'My car has broken down'

(7b) Predicate focus

(Ma voiture)	elle	est	en	PANNE
(My car)	*it*	*is*	*in*	*breakdown*

'My car/it is broken down'

(7c) Argument focus

C'est	ma	VOITURE	qui
It is	*my*	*car*	*that*
est	en	panne	
is	*in*	*breakdown*	

'It's my car that's broken down'

Reduction in Salience

Speakers and writers can treat information as available to listeners and readers. Such information is said to be given. Since it is treated as recoverable, and contrasts with information that is new and not recoverable, the constituents conveying it are not highlighted but reduced. Major phrasal categories are reduced to pro-elements or zero, as exemplified in (8).

(8a) The students went into the examination hall. They wrote their names on the script books and began to read the questions.
(8b) Bethan went to the exhibition. Catriona couldn't.
(8c) I was ill yesterday. So was my wife.

In (8a), *the students* is replaced by *they* in the second sentence and reduced to zero in the second clause of that sentence, [ ] *began to read the questions*. In (8b), *went to the exhibition* is replaced by *couldn't* [ ]; the negative *n't* adds new information. In (64c), *ill* is replaced by *so*.

Speakers referring to entities that are very salient in a given situation typically do not even use proforms. This phenomenon is known as situational ellipsis; the examples in (9) are from Quirk *et al.* (1985) with the ellipted items in bold inside square brackets.

(9a) [**I**] told you so
(9b) [**do you**] want a drink?
(9c) [**it/the restaurant/the train**] seems full

The ellipsis of constituents carrying given information can extend over various turns in a conversation. (10a) is an excerpt from real conversation with the ellipted constituents in bold. The boy mentioned in M59 is one Richard, who has been under discussion.

(10) **M1** what's he going to do, that boy, anyway?
L1 [**that boy is going to**] play golf
A1 [**that boy is going to**] be a professional golfer
M2 is he [**going to be a professional golfer**]
L2 he would [**be a professional golfer**] if he could [**be a professional golfer**] I think he's applied for a scholarship

In some languages constituents are made less salient by being moved to the right, out of the core of the clause. Vallduví (1994) gives the following examples from Catalan:

(11a)

El	Luc	[s'estima	el	GOS]
The	*Luke*	*loves*	*the*	*DOG*

'Luke loves his dog'

(11b)

El	Lluc	[se	l'ESTIMA],	el	gos
The	*Luke*	*self*	*it-LOVES*	*the*	*dog*

'Luke LOVES his dog'

(11a), with the focal accent on the rightmost constituent *gos*, is neutral. (11b) has the verb *estima* as the focal constituent. The focal accent falls on the rightmost constituent; it can fall on the verb only if the verb is rightmost. This is brought about by *el gos* being

moved rightwards out of the core clause into a position where it is clearly signaled as background, given material. Luke and the dog are given; the relationship between them is presented as new via the verb.

(12), also from Vallduví (1994), shows a real example in context. *Treballs* occurs in A's contribution and is repeated, in the NP *els treballs*, in B's, in which it is moved to the right, out of the core clause, in order to allow *macro* to be the rightmost constituent and to carry the focal accent. In English, B might have said *I thought it was the mainframe you did the papers on*.

(12a)	tinc	un	ordinador	que	va	molt
	I-have	*a*	*computer*	*that*	*works*	*really*
	bé	té,	mira	aquest	treball	
	well	*here*	*look-at*	*this*	*paper*	

(12b)	em	pensava	que	els
	I	*thought*	*that*	*them*
	feies	al macro,	els treballs	
	you-did on-the	*mainframe*	*the papers*	

Note that in B's contribution the mainframe and the papers are treated as given; they are referred to by means of definite noun phrases. What is treated as new is not *al macro*, 'on-the mainframe,' but the production of the papers on the mainframe; as Lambrecht noted, a value is assigned to *x* in the proposition *prepare papers on x*.

Introducing New Entities

Completely new entities can be introduced by the classic existential construction in (13a), in which they are highlighted by the use of a special construction and by being in final or near-final position. The possessive *have (got)* construction can be used too, as in (13b). In special circumstances, such as when two people are cooperating in a task, new entities may be introduced and made salient by the use of an interrogative possessive construction, as in (13c).

(13a) There's a Phillips screwdriver in the left-hand drawer
(13b) We have an old Volvo. It keeps going but it drinks petrol
(13c) Have you got a smithy on your map?

(13c) comes from dialogs produced by pairs of subjects carrying out a task in which one person explains to another person how to draw a route on a map. Neither person can see the map being used by the other. Entities are regularly introduced (i.e. treated as new) by means of constructions with *see*: *Can you see allotments? Can you see a windmill?* One participant injects a note of certainty by using the formula *you'll see a diamond mine on your map*, *you'll see a graveyard*. French has a similar construction, as in (14).

(14)	J'ai	mon	enfant	qui	est	malade
	I-have	*my*	*child*	*who*	*is*	*ill*

'My child is ill'

Speakers have various constructions for highlighting new propositions, which may also signal a new topic of conversation. The examples in (15) are more typical of writing but are a good starting point.

(15a) X has one interesting/obvious/relevant/important property, namely . . .
(15b) Another property of X that must be taken into account is . . .
(15c) We turn now to a less/more attractive property of X
(15d) It is worthwhile remarking at this point that . . .
(15e) Consider for a moment the fact that . . .

Other constructions are more typical of spontaneous speech. Very common is *the thing is* as in (16). (Note the use of *What about X?* to signal a change of topic, a change of what is centered).

(16a) What about Edinburgh? Do the people go up there?
(16b) oh yeah a lot
(16c) oh yes especially at night. They go to the pictures. **But the thing** is if you go to the pictures if you go to the late show you've to run for buses

The thing is is regularly reduced to *thing is*; the loss of *the* indicates that the phrase may come to be a single item no longer perceived as two words. (17) shows a common variation on *the thing is*.

(17) **the only thing with Beth** Beth'll not spend money. She's mean. She's really mean. She wouldn't give you two halfs for a one

Speakers also use free relative clauses, such as *what surprises you* in (18). *What* points forward to an upcoming explanation.

(18) **I tell you what surprises you em**//as I say . . . it's marvelous how many people stayed in such a really small area

The previous constructions are ways of highlighting new information. Speakers regularly have to highlight information (people, things, and propositions) that are given, in the sense that they have been mentioned but not recently, or are obvious in the immediate context. *You see* and *you know* are frequently used for this purpose, as in (19).

(19a) **you see Mr Y** he's got rid of whatsername the old secretary
(19b) **you see** the houses on the other side of the square?
(19c) **you know** where it says 'secret valley'?

In some varieties of English in the United Kingdom (e.g., Scottish English), *see* alone is used. Whether with *you see* or *see*, the intonation marks the construction as a question, as does the fact that listeners often respond with *yes* or *no*. Other constructions are *as for X* and *as far as X is concerned*: *As for the other candidates, they're simply not up to the job*, *As far as funding is concerned, you just leave that to the fund-raising team*.

English has two constructions that highlight old information. They are illustrated in (20) and (21).

(20) Left dislocation
(20a) what are the people like to work with the drivers
(20b) **the driver** he's really friendly and **the guy that's** full time he gives you a lot of laughs

(21) Right dislocation
(21a) they're still here, **the people from next door**
(21b) it's a dangerous pastime, **reviewing**

Ward *et al*. (2002: 1410–1411) describe left dislocation as a construction that simplifies the speaker's task of producing complex information and the listener's task of interpreting it. A point to be emphasized is that left dislocation is not a construction essentially associated with breakdown of syntax or difficulties in syntax planning. (20), from real conversation, shows no hesitations or stumbling. It allows the speaker to introduce an entity, possibly requiring a complex description, in one chunk of syntax (e.g., *the driver*) and then to provide information about that entity in another chunk (e.g., *he's really friendly*). Left dislocation is 'designed' for the production of language in real time. Of course, because the noun phrase *the driver* comes first in (20) and is outside the clause *he's really friendly*, it is highlighted. (An important fact is that left dislocation is not just typical of spoken English but is typical in the spoken Russian examined by Zemskaja (1973), the spoken French explored in Blanche-Benveniste (1991), and many other languages. It is not just an idiosyncrasy of speakers of English but seems to be a 'design feature' of spoken language in general.)

Ward *et al*. describe right dislocation as clarifying the reference of a pronoun. The right-dislocated phrases in (21), *the people from next door* and *reviewing*, are unlikely to carry the focal accent; however, where a pronoun is used to introduce a completely new entity the phrase can carry the focal accent, as in *parked right outside our door it was, a huge TRUCK*.

Cleft Constructions

English has two major constructions that serve to highlight words and phrases and the information they carry. The constructions, known as clefts, are exemplified in (22).

(22a) It's **that side** you should be on (IT cleft)
(22b) What you want to do is **curve round that wood** (WH cleft)

IT clefts can be contrastive or noncontrastive (see the previous discussion of Chafe and Lambrecht). An overtly contrastive example is in (23). The focal accent falls on the item that is being contrasted, *syntax*.

(23) we're after everything I mean not the phonetics because that's fairly well known anyway it's **the** SYNTAX we're after

(24) is a noncontrastive IT cleft.

(24) I'm supposed to have it [costume for a play] toady and I forgot all about it so I'm not very popular I don't know I think it's one of **the** TEACHERS is taking photographs but I hate having my picture taken

In spoken English speakers regularly produce a construction that has the same function as the IT clefts in (23) and (24) but is not a complete IT cleft.

(25a) when do they start again?
(25b) it's the middle of the month

The complete cleft would be *It's the middle of the month they start again* but the clause *they start again* is ellipted, for the same reason as words and phrases are ellipted in (8) and (10): in speech old information is left out, or rather the words and phrases carrying old information are left out.

The WH cleft in (22b) consists of *what you want to do* and the phrase *curve round that wood*. Two bits of syntax are connected by *is*. In spontaneous spoken English WH clefts typically consist of the WH part followed directly by a complete clause: *what you want to do-you curve round that wood*. The WH word points forward in the discourse and WH clefts can be used either to introduce a narrative or talk, as in (26), or to draw a line under a discussion and point forward to the next stage in the dialogue, as in (27).

(26a) what happened was when the school was opened the priests of the other church were chosen to be chaplains [speaker continues the tale]

(27a1) I've got a gold mine, a totem pole and then a great rock, a really good bit down
(27b1) right
(27a2) and then bandit territory right at the bottom
(27b2) right what you're trying to do is avoid the totem pole

Most of the previous examples are from English, but the Catalan examples in (11) and (12) demonstrate that the signaling of focus and the handling of old information are done differently depending on the syntactic and phonological patterns of particular languages. The functions of word order also vary from language to language, quite apart from the fact that the basic neutral word order also varies. In the examples of right dislocation in (21), the rightmost phrase typically does not carry a focal accent. In Italian, however, with more flexible word order, the rightmost phrase is typically focal. *Io pago* 'I am-paying' is a neutral reply to *What are you doing?*. *Pago io* is equivalent to *It's me that's paying (and not anyone else)*. Consider (28), in which the final word *Gino* is in contrastive focus.

(28) Non trovi anche tu che
Not find also you that
Mario è bello?
Mario is handsome
'Don't you too think that Mario is handsome?'

Non lo trovo tanto bello-
Not him I-find so handsome
è più bello Gino
is more handsome Gino
'I don't find him so handsome. Gino's more handsome'

Clefts, Word Order, and Particles

Cleft constructions are available and readily used by speakers of certain languages on the western seaboard of Europe. The availability and use of clefts declines across Europe from west to east, and the spoken language data on which this article is based indicate that nonneutral word orders are often (perhaps even typically) accompanied by particles. Speakers of English, French, and Swedish, for example, use clefts regularly. In theory, German has cleft constructions, but in the route-drawing task mentioned in connection with (13c) German participants rarely used clefts. (On the other hand, clefts do occur in German conversation.) The availability and use of clefts declines across Europe from west to east but there is an increase in the use of nonneutral word orders, often (perhaps even typically) accompanied by discourse particles or markers. (See Fraser, 1998.) (29) is a German example with the particle *eigentlich* where English-speaking participants could use a WH cleft. (For a fuller discussion, see Miller and Weinert, 1998: 297–300.)

(29) und jetzt muß du eigentlich
and now must you really
parallel zu der Linie wieder
parallel to the line again
zurückgehen
back-go
'what you have to do is go back parallel to the line . . .'

German speakers typically highlight words and phrases by means of particles such as *noch*, *sonst noch*, and *zusätzlich*. The rare WH clefts typically contain one of these particles, as in (30).

(30) was ich noch sagen wollte ich
what I still to-say wanted I
hab dir das Geld da hingelegt
have to-you the money there put
'What I wanted to say is that I've put the money there for you'

Where English uses clefts, other languages have special highlighting positions. In Finnish clauses, any item at the beginning of the clause other than the subject is highlighted. (31a) is neutral, but in (31b) the verb is highlighted and in (31c) the direct object. The appropriate English translation is by means of a discourse particle for (31b) and by an IT cleft for (31c). (32), which is the same construction in Finnish, is in context appropriately translated by a reverse cleft.

(31a) Marja tapasi Jussin Lontoossa
Mary-NOM met Jussi-ACC London-LOC
'Mary met Jussi in London'
(31b) TAPASI Marja Jussin Lontoossa
met Mary-NOM Jussi-ACC London-LOC
'Mary did indeed meet Jussi in London'
(31c) MARJA Jussin Lontoossa tapasi
Mary-NOM Jussi-ACC London-LOC met
'It was Mary who met Jussi in London'

(32) siellä sinun pitäisi olla
Where/there you-GEN should be
'That's where you should be'

Conclusion

This article began with the original concept of focus as new information signaled by a focal accent. It discussed focus and centering, focus and transition from one section of text to another, and contrastive

and noncontrastive focus. It also considered how phrases and the information they carry can be reduced in status. The second half of the article dealt with how speakers can make information salient, using different devices depending on the language. English has different constructions, such as the IT cleft and WH cleft, but also discourse particles. Other languages use word order and discourse particles. Whether speakers are introducing new entities, changing topic, emphasizing information, or contrasting one thing with another, they present the information as new and make it salient.

Focus Particles

V Gast, Free University of Berlin, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Focus particles are invariant scope-bearing elements that interact with the focus–background structure of a sentence. They express quantification over the set of alternative values contrasting with the denotation of a focus, in relation to the information given in the background of a sentence. Typical instances of focus particles are English *only*, *also*, and *even*. For example, *only* in *Only* $[Fred]_F$ *snores* expresses that the property of snoring (background) can be attributed to no one other than Fred (focus).

The meaning of focus particles can be described with reference to two major parameters. First, there are two basic types of quantification: While *only* conveys negated existential quantification over the domain of alternative values and is, in that sense, 'exclusive,' *alo* and *even* express existential quantification and are therefore 'additive' or 'inclusive.' Second, some focus particles interact with unstructured sets of alternative values (nonscalar particles, e.g., *too*), whereas others make reference to ordered sets of alternatives (scalar particles, e.g., *even*). For example, *Peter snores, too* merely presupposes that there is someone other than Peter who snores, while *Even Peter snores* additionally suggests that Peter is particularly unlikely to snore.

Focus particles may stand in various structural relationships to the corresponding foci. There are three major types of configurations: (i) the particles

and noncontrastive focus. It also considered how phrases and the information they carry can be reduced in status. The second half of the article dealt with how speakers can make information salient, using different devices depending on the language. English has different constructions, such as the IT cleft and WH cleft, but also discourse particles. Other languages use word order and discourse particles. Whether speakers are introducing new entities, changing topic, emphasizing information, or contrasting one thing with another, they present the information as new and make it salient.

Focus particles are invariant scope-bearing elements that interact with the focus–background structure of a sentence. They express quantification over the set of alternative values contrasting with the denotation of a focus, in relation to the information given in the background of a sentence. Typical instances of focus particles are English *only*, *also*, and *even*. For example, *only* in *Only* $[Fred]_F$ *snores* expresses that the property of snoring (background) can be attributed to no one other than Fred (focus).

The meaning of focus particles can be described with reference to two major parameters. First, there are two basic types of quantification: While *only* conveys negated existential quantification over the domain of alternative values and is, in that sense, 'exclusive,' *alo* and *even* express existential quantification and are therefore 'additive' or 'inclusive.' Second, some focus particles interact with unstructured sets of alternative values (nonscalar particles, e.g., *too*), whereas others make reference to ordered sets of alternatives (scalar particles, e.g., *even*). For example, *Peter snores, too* merely presupposes that there is someone other than Peter who snores, while *Even Peter snores* additionally suggests that Peter is particularly unlikely to snore.

Focus particles may stand in various structural relationships to the corresponding foci. There are three major types of configurations: (i) the particles

exhibit a considerable degree of positional variability but must c-command the focus (e.g., English *only*); (ii) the particles are adjacent to the focus (e.g., Turkish *de* 'too'); or (iii) the particles occupy a fixed position in the clause (e.g., the preverbal position in Mandarin Chinese). A tendency has been observed for exclusive particles to precede the focus, whereas inclusive particles often follow it (König, 1991).

Some focus particles exhibit specific compatibility requirements on their environment, for example, insofar as they interact only with foci of specific syntactic categories (e.g., Standard German *selbst* 'even' co-occurs only with clausal and nominal foci). Moreover, additive focus particles are sometimes sensitive to the polarity of a sentence (e.g., English *too* vs. *either*; Spanish *tambien* 'too' vs. *tampoco* 'either').

The historical sources of focus particles cover a wide range of expressions. Exclusive particles typically develop from elements meaning 'one' or 'alone' (e.g., English *only* < ME *oon-li* 'one-ADV'; French *seule-ment* 'alone-ADV') or 'not more/in addition/except' (e.g., Modern Breton *hepken* < *hep ken* 'without more'; Danish *kun* < *ikke uden* 'not except'). Adjectival sources with a 'privative' meaning are also widespread (e.g., Swedish *bara* < *ber-* 'bare'; German *bloß* 'bare'), whereas verbal source lexemes are relatively rare (e.g., German *nur* < MHG *ne wære* 'not was.CONJ'). Additive focus particles are often diachronically related to meanings such as 'and (so)' (e.g., Danish *og-så* 'and-so') or to expressions indicating 'increase' (e.g., English *too* < OE *tō* 'in addition'). Among the most typical source lexemes giving rise to scalar additive focus particles are 'until' (e.g., Spanish *hasta*; Hausa *har*), intensifiers (e.g., French *même*; Finnish *itse*), and meta-linguistic expressions such as 'really,' 'truly' or 'clearly' (e.g., Romanian *chiar* < *clarus/a* 'clear').

Fodor, Jerry (b. 1935)

S-H Seong, University of Bonn, Bonn, Germany

© 2006 Elsevier Ltd. All rights reserved.

Jerry Alan Fodor (born in 1935) is the State of New Jersey Professor of Philosophy at Rutgers University. He earned his Ph.D. in Philosophy from Princeton University in 1960. He previously held professorships at the departments of philosophy and psychology at MIT and at the CUNY Graduate Center.

Fodor's work focuses on the philosophical problems about psychology, philosophy of mind, philosophy of language, theories of cognitive architecture (modularity, interactionism, etc.), psycholinguistics (especially parsing), and child's theory of mind. His experimental work especially emphasizes the last two topics.

Fodor has busied himself with the problem of how mental representation can be accounted for within a physicalist framework. His theory is sometimes labeled as 'Computational Representation Theory of Mind.' He is known for his thesis of 'radical concept nativism,' which posits that virtually all lexical concepts are innate. In one of his representative works, *The mind doesn't work that way: the scope and limits of computational psychology* (Fodor, 2000), he examines the relationships among the computational and modular theories of mind, nativism, and evolutionary psychology.

Fodor takes the view that "computational theory of mind (CTM)" supported by Steven Pinker (1997) does not suffice to explain the nature of human thought, even though the theory turns out to be the best theory of cognition at hand. CTM maintains that the mind is a system of organs of computation and that the mental processes of human beliefs and desires are mechanical computations and function like syntactic operations of algorithmic structures. According to Fodor, however, problems crop up when it comes to cases where the mental process must be dependent on factors outside the syntactic domain of the mental representation in question. As the main alternative to the CTM, connectionism is also critically evaluated by Fodor; according to him, it fails to explain abductive reasoning. In Chapter 5 of *The mind doesn't work that way*, Fodor also argues that evolutionary psychologists, such as Steven Pinker, are misguided in their thinking that human minds are adaptations or products of natural selection, since it is likely that human minds evolved quickly as saltations rather than gradually as the product of mutations of small and incremental effect. Fodor believes that gradualism is a requirement of natural selection, while

exhibit a considerable degree of positional variability but must c-command the focus (e.g., English *only*); (ii) the particles are adjacent to the focus (e.g., Turkish *de* 'too'); or (iii) the particles occupy a fixed position in the clause (e.g., the preverbal position in Mandarin Chinese). Fodor, Jerry (b. 1935)

S-H Seong, University of Bonn, Bonn, Germany

© 2006 Elsevier Ltd. All rights reserved.

Jerry Alan Fodor (born in 1935) is the State of New Jersey Professor of Philosophy at Rutgers University. He earned his Ph.D. in Philosophy from Princeton University in 1960. He previously held professorships at the departments of philosophy and psychology at MIT and at the CUNY Graduate Center.

Fodor's work focuses on the philosophical problems about psychology, philosophy of mind, philosophy of language, theories of cognitive architecture (modularity, interactionism, etc.), psycholinguistics (especially parsing), and child's theory of mind. His experimental work especially emphasizes the last two topics.

Fodor has busied himself with the problem of how mental representation can be accounted for within a physicalist framework. His theory is sometimes labeled as 'Computational Representation Theory of Mind.' He is known for his thesis of 'radical concept nativism,' which posits that virtually all lexical concepts are innate. In one of his representative works, *The mind doesn't work that way: the scope and limits of computational psychology* (Fodor, 2000), he examines the relationships among the computational and modular theories of mind, nativism, and evolutionary psychology.

Fodor takes the view that "computational theory of mind (CTM)" supported by Steven Pinker (1997) does not suffice to explain the nature of human thought, even though the theory turns out to be the best theory of cognition at hand. CTM maintains that the mind is a system of organs of computation and that the mental processes of human beliefs and desires are mechanical computations and function like syntactic operations of algorithmic structures. According to Fodor, however, problems crop up when it comes to cases where the mental process must be dependent on factors outside the syntactic domain of the mental representation in question. As the main alternative to the CTM, connectionism is also critically evaluated by Fodor; according to him, it fails to explain abductive reasoning. In Chapter 5 of *The mind doesn't work that way*, Fodor also argues that evolutionary psychologists, such as Steven Pinker, are misguided in their thinking that human minds are adaptations or products of natural selection, since it is likely that human minds evolved quickly as saltations rather than gradually as the product of mutations of small and incremental effect. Fodor believes that gradualism is a requirement of natural selection, while

saltationism is opposed to small, incremental variations of fitness.

Jerry Fodor is also known as one of the leading adherents of naturalized semantics, or informational semantics. This has to do with interpreting the connection between meanings and representations. A meaning of a sentence is represented in some sort of internal code or 'language of thought.' Semantically equivalent expressions must denote the same entities, so concepts that carry identical information should be interpreted as coextensive, otherwise the theory of content cannot be purely informational. According to informational semantics, "a predicate's content consists of the information it carries, which in turn consists of the property whose instantiation would, under standard conditions, lawfully covary with the occurrence of the predicate" (Wakefield, 2003: 525).

Folk Etymology

L Bauer, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

'Folk etymology' or 'popular etymology' is the name given to a process of reanalysis. Speakers of a language, expecting their words to be partly motivated, find in them elements which they perceive as motivating the word, even where these elements have no historical presence. It is called 'folk' or 'popular' because it pays no attention to the knowledge of the erudite. It is called 'etymology' because it appears to invent a new origin for a word, an origin which is contrary to fact. A better label would be 'morphological reanalysis.'

A set of words particularly susceptible to folk etymology is loan words. Very often these obtain forms in the borrowing language which show something of the way they have been perceived, but owe little to the structure of the language from which the word is borrowed, except some superficial phonetic resemblance. Examples include English *woodchuck* from Ojibwa *otchig*, with nothing to do with either wood or throwing; Danish dialect *kamelte* (literally 'camel tea') from *kamillete* ('chamomile tea'); German (Standard German) *Hängematte* (literally 'hanging mat') originally from Taino *hamaca* 'hammock.'

The source word need not, however, be a foreign word; it can be native. Consider English *titmouse*, a kind of bird, from an earlier *titmāse*, with no link to mice, or German (Standard German) *Maulwurf* 'mole' (literally 'mouth throw') from an earlier *moltwerf* 'earth thrower' (compare English dialect *mouldywarp*). The same word turns up in one attested (but not established) instance in Danish as *muldhvalp* (literally 'earth puppy'). Note also that folk etymology frequently leaves part of the original

saltationism is opposed to small, incremental variations of fitness.

Jerry Fodor is also known as one of the leading adherents of naturalized semantics, or informational semantics. This has to do with interpreting the connection between meanings and representations. A meaning of a sentence is represented in some sort of internal code or 'language of thought.' Semantically equivalent expressions must denote the same entities, so concepts that carry identical information should be interpreted as coextensive, otherwise the theory of content cannot be purely informational. According to informational semantics, "a predicate's content consists of the information it carries, which in turn consists of the property whose instantiation would, under standard conditions, lawfully covary with the occurrence of the predicate" (Wakefield, 2003: 525).

Folk Etymology

L Bauer, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

'Folk etymology' or 'popular etymology' is the name given to a process of reanalysis. Speakers of a language, expecting their words to be partly motivated, find in them elements which they perceive as motivating the word, even where these elements have no historical presence. It is called 'folk' or 'popular' because it pays no attention to the knowledge of the erudite. It is called 'etymology' because it appears to invent a new origin for a word, an origin which is contrary to fact. A better label would be 'morphological reanalysis.'

A set of words particularly susceptible to folk etymology is loan words. Very often these obtain forms in the borrowing language which show something of the way they have been perceived, but owe little to the structure of the language from which the word is borrowed, except some superficial phonetic resemblance. Examples include English *woodchuck* from Ojibwa *otchig*, with nothing to do with either wood or throwing; Danish dialect *kamelte* (literally 'camel tea') from *kamillete* ('chamomile tea'); German (Standard German) *Hängematte* (literally 'hanging mat') originally from Taino *hamaca* 'hammock.'

The source word need not, however, be a foreign word; it can be native. Consider English *titmouse*, a kind of bird, from an earlier *titmāse*, with no link to mice, or German (Standard German) *Maulwurf* 'mole' (literally 'mouth throw') from an earlier *moltwerf* 'earth thrower' (compare English dialect *mouldywarp*). The same word turns up in one attested (but not established) instance in Danish as *muldhvalp* (literally 'earth puppy'). Note also that folk etymology frequently leaves part of the original

word unanalyzed: *belfry*, from an earlier *berfry*, analyzes the first element as related to *bell*, but leaves the *-fry* element meaningless.

The line between an instance of folk etymology and a malapropism is sometimes a thin one, but in principle a malapropism confuses two similar-sounding words (e.g., in an example from Sheridan's character Mrs. Malaprop, *contiguous* and *contagious*) while folk etymology is an error based on the supposed meaning of elements within the word (even if those elements are clearly absurd, like the *mouse* in *titmouse*) which spreads beyond the individual to a whole community. Both are often occasioned by the attempt to use exotic or difficult vocabulary whose form is not entirely accurately perceived.

Folk Linguistics

D R Preston, Michigan State University, East Lansing MI, USA

© 2006 Elsevier Ltd. All rights reserved.

In the world outside linguistics, people who are not professional students of language nevertheless talk about it. Such overt knowledge of and comment about language by nonlinguists is the subject matter of folk linguistics. Although study of folk linguistics is older, interest was reawakened at the 1964 University of California, Los Angeles, Sociolinguistics Conference:

> We should be interested not only in (*a*) what goes on (language), but also in (*b*) how people react to what goes on (they are persuaded, they are put off, etc.) and in (*c*) what people say goes on (talk concerning language). It will not do to dismiss these secondary and tertiary modes of conduct merely as sources of error. (Hoenigswald, 1966: 20)

Hoenigswald's plan for the study of folk linguistics (*c* above) included collections of folk expressions for speech acts and even of folk terminology for and definitions of such grammatical categories as 'word' and 'sentence.' He proposed uncovering folk accounts of homonymy and synonymy, regionalism and language variety, and social structure (e.g., age and sex). He suggested that particular attention be paid to folk accounts of the correcting of linguistic behavior, especially in the context of first language acquisition and in relation to ideas of correctness and acceptability. He recommended asking what sorts of language and speech styles are admired and what sorts have special status as taboo. He urged researchers to seek folk linguistic accounts of both language history and deficit (e.g., stuttering and muteness).

Here 'folk' refers to those who are not trained professionals in the area under investigation. It does not refer to rustic, ignorant, uneducated, backward, so-called primitive, minority, isolated, marginalized, or lower-status groups or individuals. Included in the research on folk linguistic belief in the United States speech community most often cited in this entry, for example, are respondents who know the names of Noam Chomsky, Dell Hymes, and William Labov. To do otherwise would be to assume that folklore and cultural anthropology are not doable in some societies. Another important importation from modern folklore into folk linguistic research is the notion that folk belief is simply belief, its folk character being no indication of its truth or falsity.

Hoenigswald's suggestions have been taken up recently, and the discrediting of folk belief has been rejected, but even those who would agree that folk belief is worthy of investigation have raised objections – one that suggests that folk linguistics is impoverished, particularly in the English-speaking world, and another that suggests it is largely inaccessible.

The impoverishment issue was raised by William Labov, immediately following Hoenigswald's 1964 presentation:

> The overt responses in American and English society generally are quite poor as far as vocabulary is concerned. 'Poverty-stricken' would be the best term for this vocabulary. The inadequacy of people's overt remarks about their own language is directly reflected in the fact that there are only a few words that they use to convey the subjective response that they feel . . . . But some of the references made here today show that there are highly institutionalized folk attitudes toward language which are much richer than those which we

> are accustomed to meeting in the U.S. and England. (discussion by Labov in Hoenigswald, 1966: 23)

If one could show a strong pattern of "subjective response" that the folk were interested in talking about but were incapable of talking about due to vocabulary deficiency, then one might say that a language (or variety) was inadequate, but Labov himself singles out linguistic features for which the folk have such labels and makes the point that they are linguistic stereotypes, items that are the subject matter of overt comment (e.g., Labov, 1972: 248). When the folk are vague, confused, or simply wrong about linguistic phenomena, it is often in their responses to linguists, which may prove only that linguists either ask about objects of no interest to the folk or fail to account for the adequacy of the folk notion.

One appropriate treatment of folk responses tries to set them in a dynamic context of use, not in a static one of folk knowledge. This allows one to find a detailed folk linguistics, one operating at many levels of linguistic structure and in many areas of concern. Joel Sherzer reflects this attitude in his comment on folk names for ways of speaking:

> Terms for talk ... are communicative resources which vary from person to person and from context to context and are used strategically in the course of speaking. In addition, there are significant features of ... language and speech that are not labeled, and there are labels that are ambiguous without reference to contextualization in concrete instances of usage. (Sherzer, 1983: 16)

The second impediment to folk linguistic research is the inaccessibility to folk consciousness of linguistically interesting matters. Michael Silverstein (1981) attempts to describe the sorts of language features that are available to folk awareness and suggests five conditions: (a) unavoidable referentiality, (b) continuous segmentability, (c) relative presuppositionality, (d) decontextualized deducibility, and (e) metapragmatic transparency.

Silverstein illustrates 'unavoidable referentiality' with the deference-to-hearer versus solidarity-with-hearer pragmatic system, realized as a second or third person plural (deferential) versus a second person singular (solidary) – e.g., German (German, Standard) *Sie* versus *du*; French *vous* versus *tu*. The opposition is unavoidably referential, for the pronoun forms that carry the pragmatic system are the same ones that refer to individuals (Silverstein, 1981: 5). In contrast, although a speaker's selection of a certain phonetic variant in a given performance might symbolize greater deference to a hearer (as a result of the greater formality associated with that variant), such variants are not themselves referential; therefore, although formality versus informality is a pragmatic opposition, its realization in the use of a particular phonetic variant is not unavoidably referential and less open to folk awareness.

The second of Silverstein's requirements is 'continuous segmentability.' Some linguistic units are not interrupted by other material. In *I am going to town*, the entire sentence, each word, phrases such as *to town*, and even morphemes such as *-ing* are all continuously segmentable. The form that refers to the progressive aspect, however, is *am -ing* and displays discontinuity, making it less open to awareness (Silverstein, 1981: 6). However, in a lengthy discussion of the passive, an equally discontinuous phenomenon, several U.S. English-speaking respondents provided evidence for considerable awareness of the-construction (Niedzielski and Preston, 2003). Subject–verb agreement, multiple negation, and so-called split infinitives, all discontinuous or potentially so, are also frequently discussed phenomena in English, suggesting that some other factors may overcome Silverstein's purely linguistic categorizations.

'Relative presuppositionality' is Silverstein's term for the degree to which a pragmatic function depends on contextual factors to realize its meaning. At one end of this scale are such items as *this* and *that*, which successfully function only if there is a physical reality to which they can be linked, a relative physical (or mental) distance that supports the choice between them, or a prior mention of some entity (Silverstein, 1981: 7). Such presuppositionally dependent items do very little creative work and, according to Silverstein, are readily available to the folk as linguistic objects. At the other end of the scale are items that are context creating. For example, Duranti (1984) notes that third person subject pronoun occurrence in Italian (a pro-drop language) signals a "main character" and usually one toward whom the speaker displays "positive affect." This function of such pronoun appearance in Italian is hidden to folk speakers.

Silverstein's 'decontextualized deducibility' says more about how linguistic facts are accounted for by the folk than about their general availability. Silverstein claims that one common path taken by folk commenters on linguistic objects is that of specifying the 'deducible entailed presuppositions,' a characterization that, he says, is the equivalent of stating the meaning. In other words, providing the contexts in which the form in question fits or is true is a common folk activity (Silverstein, 1981: 13–14).

The fit between increasingly specified contexts and a word's appropriate use is explicitly remarked on by D, a folk respondent, in the following:

((In a discussion of Christmas customs, H (the fieldworker) has asked if there is any difference between *gift* and *present*. D has said earlier that there is not, but he returns to the question.)) [In this and following quotations of respondent discourse, the transcription conventions follow those devised by Gail Jefferson (Niedzielski and Preston, 2000).]

D: Oftentimes a gift is something like you you go to a Tupperware party and they're going to give you a gift, it's- I think it's more=

[
H: Uh huh.
D: =impersonal, - than a present.
[
G: No, there's no difference.
[
D: No? There's real – yeah there's really no difference. That's true. Maybe the way we use it is though.
[
G: There is no difference.
U: Maybe we could look it up and see what 'gift' means.
[
D: I mean technically there's no difference.
((They look up *gift* and *present* in the dictionary.))

D's distinction between 'technical' meaning and 'use' points in the direction of 'decontextualized deducibility'; that is, although D feels the words mean the same at a level open to expert knowledge, the fit of the words into different contexts reveals distinctions. After some time, he comes up with an appropriate frame:

D: In advertising sometimes they'll say: you know, 'We have a gift for you.' Or- or something.
H: Yes, yes. But they don't use 'present.'
D: Um : – I don't think as much.

D goes on to say that his bank offers a *gift* if one opens an account and that *present* would be unlikely in that context. This finely tuned characterization of meaning is determined through the folk activity of matching the item to those contexts that meet the required characteristics.

Finally, Silverstein's 'metapragmatic transparency.' When the folk characterize what went on, they are more likely to mimic what was actually said if the performance is 'metapragmatically transparent.' Suppose that Wanda is cold and that Karla is near the thermostat. Wanda has a number of options:

Brrrrrrrrr!
I'm freezing.
Aren't you cold?
I wonder if the furnace is broken?
Would you mind if we had a little more heat in here?
Turn up the heat.

'Turn up the heat' obviously has the greatest metapragmatic transparency, and folk accounts of the interaction between Wanda and Karla are more likely to result in an observation that *Wanda asked Karla to turn up the heat* than in an embedding of any of the other request forms. *Wanda said "Aren't you cold," and by that meant for Karla to turn up the heat* would be a strange report (except for a linguist or a philosopher).

Silverstein's account of the potential for folk awareness of linguistic structure does not, however, address the types of awareness evidenced in actual reports (or failures to report). In an effort to so classify actual occurrences, Preston (1996a) proposed the following modes of awareness:

(a) *Availability*: As already suggested, not all facets of language (whether of performance, ability, or reaction) have equal availability to the folk. They may be ranked as follows:
   (i) *Unavailable*; the folk not only do not but will not comment on such topics (e.g., specific phonological features of some so-called accents).
   (ii) *Available*; the folk will discuss some matters carefully described by a fieldworker (e.g., deviant sentences), but they do not normally do so.
   (iii) *Suggestible*; although seldom initiated in ordinary conversation, the folk will comment on topics if they arise, and they do not require elaborate description from a fieldworker.
   (iv) *Common*; topics of usual folk linguistic discussion.

(b) *Accuracy*: Although it has no bearing on the value of the data, folk descriptions of every aspect of language may be inaccurate or accurate.

(c) *Detail*: A linguistic object may be characterized with great specificity or none.
   (i) *Global*; in a) i) above, for example, the phonological detail of an accent might be unavailable, but that does not limit comment on the accent.
   (ii) *Specific*; in some cases, linguistic characterization is detailed (e.g., accounts of speakers who are said to drop their g's in *-ing* forms).

(d) *Control*: In both account and performance, folk linguists may or may not control the variety

> (or any aspect of it) under consideration. This cuts across the first three considerations in unexpected ways. A speaker who reports on only the global aspects of an accent might nevertheless give a detailed imitation of it (which might be in part accurate, in part inaccurate, e.g., white imitations of African-American English and African-American imitations of white English, Preston, 1992) (41–42).

A further word about 'available' is in order, for some may wonder how the folk can have a folk linguistics about matters they are led into. Folk belief is, in fact, not only a static set of wisdoms trotted out at opportune or culturally caricaturistic moments; it is also the dynamic process that allows nonspecialists to provide an account of the environment, some parts of which have been so frequently focused on in traditional reasoning that the results have come down neatly prepackaged. These should not be ignored, but respondents should also be presented with problems and areas that expose the processes of their thinking about language, even taking them down paths they have not trod. This is a productive way to discover folk concepts, for it is more like the real world of problem solving. Toelken states this notion clearly for folk studies in general:

> We might characterize or describe the materials of folklore as "tradition-based communication units exchanged in dynamic variation through space and time." *Tradition* is here understood to mean not some static immutable force from the past, but those pre-existing culture-specific materials and options that bear upon the performer more heavily than do his or her own personal tastes and talents. We recognize in the use of *tradition* that such matters as content and style have been for the most part passed on but not invented by the performer. *Dynamic* recognizes, on the other hand, that in the processing of these contents and styles in performance, the artist's own unique talents of inventiveness *within* the tradition are highly valued and are expected to operate strongly . . .. Folklore is made up of informal expressions passed around long enough to have become recurrent in form and content, but changeable in performance. (Toelken, 1979: 32)

The accuracy of folk linguistic report, however, may be a more interesting consideration than it is in the study of many other forms of folk behavior, for the path from linguistic facts to comments about them is a rocky one, impeded by the nature of communication itself as well as by social factors that accompany every linguistic act.

First, it seems clear that the structural elements of the language are subservient to communicative function so far as the folk are concerned. Even discourse analysts, who are very sensitive to minor variation, make numerous transcription mistakes, for it is difficult to turn off one's attention to communication and listen only to the form of a message. If one reports that a speaker uttered *he decided that he would go* when what he or she actually said was *he decided to go*, there is nothing lost to communication, and such 'mishearings' are very common.

Second, even if communicative function has not hidden the linguistic form, the interference of social factors may. There is no more telling example of the massive influence of stereotype than that reported in an experiment conducted by Frederic Williams and his associates (1971). The voice of a standard-English-speaking Anglo child was played while the side view (to prevent lipreading) of an Anglo, an African-American, or a Mexican-American child was shown. The respondents (teacher education majors) rated the standard speech as significantly less standard when it was accompanied by the visual image of a minority child. In fact, when the minority children's images were shown with accompanying nonstandard performances, there was no significant decrease in the teachers' ratings of their standardness.

In short, the communicative function of language is so strong that it overcomes the ability to give an accurate report of performance, whether of self or of others and whether of general or restricted phenomena. In addition, the inaccuracy of self and other report when stereotypes are engaged is also very powerful.

It is possible, however, to go further in characterizing why the folk perceive what they do. Nonlinguists, at least as seen in work done in the United States, use **pre**scription (at nearly every linguistic level) in **de**scription; linguists, on the other hand, find the sources for prescription outside language itself – in power, esteem, tradition, and the like. To be sure, the folk associate language facts and social groups, but they reject the cause and effect relationship: good language is not standard because it is used by stereotypically good people. Standard language for the folk is good because it is logical, clear, continuous (in an etymological sense), and so on. For the folk this notion of the standard extends itself even to the boundaries of what a language is. What is not a part of that logical, continuous entity is not really language at all, and appeals to dictionaries and grammars are, therefore, not appeals to trusted authorities on usage; they are appeals to pundits and sages who have some insight into an abstraction that is the only authentic language for the folk. If these guardians of the public linguistic trust fail in their responsibility to provide an accurate account of the abstraction, they may be open

to public outcry. The vehemence with which some receive news of language specialists' abrogation of their responsibility to describe the abstraction is best exemplified in the flurry of emotion that accompanied the publication of the partly usage-based *Webster's third new international dictionary, unabridged*. There is a good account and analysis of these reactions in Finegan (1980: 116–129). The majority of contributions to Greenbaum (1985) discuss such matters, and the 'Introduction' to Ferguson and Heath (1981) reviews several "American myths about language."

Recall that D (cited above) contrasts "the way we use it" with "technically" in determining the difference between *gift* and *present*. Many linguists will find this naive, for "the way we use it" is the determiner of the sense. D, like other folk linguists, however, believes that there is some sort of abstract reality to the language itself, in which, apparently, these two words mean the same thing.

In addition, what many have to say about the facts of language will appear to professional linguists to be filtered through reactive, attitudinal factors. Folk observations, however, may often reflect only the difference between a belief in a technical abstraction (the language itself) and what is actually done, but this philosophical (or Platonic) prescriptivism is not the outpouring of an overactive linguistic insecurity. An area in the upper Midwest of the United States, where a great deal of folk linguistic research has been done, has no such self-image, yet this belief in the abstraction is very common.

Figure 1 contrasts a folk versus a linguistic taxonomy. Linguists agree that there is considerable variation among individuals and types of individuals, but THE LANGUAGE in the linguistic taxonomy is a convenient fiction for certain sorts of research.

> Of course, it is understood that speech communities in the Bloomfieldian sense – that is, collections of individuals with the same speech behavior – do not exist in the real world. Each individual has acquired a language in the course of complex social interactions with people who vary in the ways in which they speak and interpret what they hear and in the internal representations that underlie their use of language . . . . We abstract from these facts . . . , considering only the case of a person presented with uniform experience in an ideal Bloomfieldian speech community with no dialect diversity and no variation among speakers. (Chomsky, 1986: 16–17)

At the level of THE LANGUAGE in the 'Linguistic' Theory, therefore, dialectal, stylistic, and even individual diversity is edited out, so this abstraction does not represent a cognitive, internal reality of an individual speaker but has been treated as one for research purposes.

Figure 1 Folk and linguistic taxonomies (partial) of competence and performance.

Figure 1 shows the radical difference between the folk and linguistic taxonomies. Linguists have created an agreed-on but fictitious abstraction (THE LANGUAGE) by pretending that there is a group of error-free, monodialectal, monostylistic speakers. The upward-pointing arrow shows that linguists know that the real basis of language, however, is embedded in the brains of individual speakers. The folk, in contrast, appear to believe in their abstraction (also called THE LANGUAGE), but the downward-pointing arrow shows that, since they take it to be real, they also believe that individual language competencies somehow derive from it.

Linguists know, however, that varieties (in fact, idiolects themselves) are the only authentic cognitive examples of THE LANGUAGE, and a linguist is just as happy to write the mid-level rules of Swiss German or Schwabian as he or she is to write the rules of so-called Standard German, or Hochdeutsch. Any of these specific varieties is equally part of the basis for the abstraction "German"; for the folk, however, such varieties deviate from the single abstraction, an idealized but nevertheless real element for them.

Teachers of introductory linguistics will recognize another outcome of this folk belief: it is only the abstraction that is rule governed; the deviations are not. The linguist's rules of African-American English or lower-class New York City English are nonsense for the folk. What rules could there be when the forms under discussion are simply failures to observe the rules of THE LANGUAGE?

The folk interpretation of the nature of language, or theory of language, has been dwelt on at length, for it is a common theme in much of what the folk say about language, and no matter what the search for underlying folk theories turns up, a responsible investigation will seek just such levels, ones of the sort suggested in recent studies of 'cultural models.'

> A cultural model is a cognitive schema that is intersubjectively shared by a social group .... One result of intersubjective sharing is that interpretations made about the world on the basis of the folk model are treated as if they were obvious facts of the world .... A second consequence of the intersubjective nature of folk models is that a great deal of information related to the folk model need not be made explicit. (D'Andrade, 1987: 112–113)

The considerations so far would suggest that the contrast between conscious and unconscious behavior characterizes the distinctness of folk linguistics from the covert structural knowledge of language (competence) and from some, perhaps many, attitudinal responses, but this contrast is perhaps better seen as a continuum than as a sharp break. Figure 2 shows that the largely unconscious sorts of reactions tapped in traditional language attitude studies may be placed in one corner of a triangle of linguistic concerns (the bn corner), and the conscious sorts of expressions of folk linguistics in the b1 corner. In both cases, a connection is made to the underlying beliefs (b′) that stand in the same relation to folk linguistic comment and attitudinal reactions as the cognitive underpinnings of language (a′) do to language production (a).

The two corners (b1 and bn) are extremes of a continuum that reaches from the most conscious, deliberate statements about language all the way to the most automatic, least-controlled attitudinal reactions to it.

The leftmost (b1) corner of this triangle is the territory most characteristic of folk linguistics, but it would be foolish to say that folk linguistics stops precisely at b23 (or b48, or any other point along the continuum) and that everything to the right of it belongs to the social psychology of language, language attitude study, or some other approach.

From this point of view, in folk linguistics, it is important to keep in mind the diversity of the objects of research (i.e., the data from a and a′), the levels of awareness (i.e., the b continuum), and the means of data collection and analysis. For example, one may investigate folk linguistics based on (1) any aspect of a or a′ (from phonetics through pragmatics and interaction, including all cognitive or psycholinguistic aspects of the storage, acquisition, and implementation of all structural levels of language), (2) the most

Figure 2 A triangle of concerns in the study of language (Niedzielski and Preston, 2003).

overtly conscious commentary about language (b1) to the most deeply subconscious reaction to a language fact (bn), and (3) methodological perspectives ranging from the carefully controlled experimental presentation of data to freewheeling conversations.

This diversity of data types, levels of awareness, and methodologies suggests that even those data that come from the conscious end of the continuum are open to investigation that may reveal the b′ features lying behind them, and this is a primary reason for the investigation of the discoursal side of folk linguistics. The following illustrations of folk linguistic research begin, therefore, on the far left side of the triangle – data acquired from the respondent when he or she is fully aware that the focus of the investigator is on the topic of language and he or she responds discursively.

In an investigation of Japanese attitudes toward English and Japanese, Imai (in Niedzielski and Preston, 2003) shows how an analysis of discoursal structure helps in understanding speaker beliefs about and attitudes toward language. She triggered the conversation by asking simply, "What do you think about the differences and similarities between Japanese and English?" She analyzed a portion of the conversation between two respondents as an 'argument' (following Preston, 1993, 1994), a discourse genre that consists, essentially, of positions, disputes, and supports.

One important part of Imai's investigation lies in her discovery that a young female respondent, Y, based her comments on a theory of what might be called the social use of language; for example, she did not regard aspects of a language to be viable parts of

it unless they were used in ordinary conversation. Evidence for this folk theory came mostly from the respondent's support moves rather than from any positions she took in the argument. Her interlocutor, for example, asserted that English has more words than Japanese, but Y disputed that position and supported her dispute with the claim that "Americans don't use difficult words." When her interlocutor asked if it weren't the case that books can be linguistically difficult, Y noted that she was concerned only with conversation. Later she also noted that she did not consider phone calls from salespersons to be authentic language either, since scripted calls were also filled with difficult and incomprehensible language, the sort she had not encountered face to face.

Imai suggested that Y's continuing support for the notion that authentic language is based on conversational usage led her to be critical of what she saw as an American insensitivity to demands for flexibility in language use.

> Y: This is not about the words and probably it is because of the national traits, but, well, I don't know how to say this, but sometimes if I said something and they didn't understand, they say they don't understand, right? And if they say 'say it again,' a Japanese would change the words or make it simpler=
> S: ((laughter))
> Y: =We try to make it simpler and explain, don't we? Americans repeat exactly the same thing.
> All: ((laughter))
> Y: They are not very flexible, you know?
> (Niedzielski and Preston, 2003: viii–ix)

Y's theory of good language included sensitivity to the needs of the interlocutor, and she clearly found Americans lacking in this respect. In contrast, the major folk notion attached to language among U.S. respondents reported above nearly always hinged on prescription. Y's comments suggested that the Japanese may base evaluative notions of language more on the area of speaker and hearer rights and responsibilities. If that is so, it may even prove to be the case that the underlying representation of language itself for Japanese speakers is not the idealized, cognitively external code held to be the essence of language by U.S. respondents.

Here is another discoursal candidate for analysis, quoted from a southeastern Michigan middle-aged, middle-class, female European-American respondent.

> M: Yeah, ah see that – that's what upsets me. You can see a really – an educated Black person, I mean I- you know I don't care what color a person is. It doesn't matter to me. – And you can underSTAND them and you can TALK to them and – Look at on the news, all the news broadcasters and everything. They're not talking ((lowered pitch)) 'Hey man, ((imitating African-American speech)) hybyayhubyhuby.' You can't understand what they're saying. And – I just don't think there's any excuse for it. It's laziness and probably – maybe it is you know, because they are low class and they don't know how to bring themselves up or they just don't want to.

This is very clearly a discourse that has language (the unintelligibility of African American Vernacular English (AAVE) and the irresponsibility of those who speak it) as its topic. M's notice of AAVE is motivated by two conditions common in folk linguistics: first, AAVE is different from her own variety (a linguistically internal reason), and second, it is clearly not a prized or correct variety (a linguistically, or structurally, external reason). M also employs a performance to focus the listener's attention on the fact that AAVE is indeed unintelligible by providing a string of nonsense syllables, presumably an imitation of the acoustic affect AAVE has on M, but surely one she expects will ring true to her listener.

Just as the investigation of the Japanese folk theory reported on above used conversational support, another rich territory to mine for folk belief about language may be the presuppositions that lie behind folk comment – the variety of unasserted folk beliefs that members of speech communities share. Linguists and philosophers alike agree that presuppositions form the backbone of mutual understanding among conversational participants.

> Presuppositions are what is taken by the speaker to be the *common ground* of the participants in the conversation, which is treated as their *common knowledge* or *mutual knowledge*. (Stalnaker, 1978: 320, emphasis in the original)

It should go without saying that the deeper the sense of community or shared culture among participants, the more likely that enormous amounts of presupposed (and therefore usually unstated) beliefs will play an important role.

With this understanding in mind, let us return to M, who states very directly why some African-Americans speak a variety that she cannot understand – they are lazy. M may feel this is a little too blunt, for she goes on to excuse this behavior by noting that such speakers are low class and don't know how to escape that situation, although she is also quick to add that it may be that "they just don't want to."

M further notes that "an educated Black person" can be understood and can be talked to (after the disclaimer that she does not care what color a person is), but she says she cannot understand other African-Americans (and she gives a little imitation of how

they talk, which, except for "Hey, man," does not even consist of words).

Her first important folk claim is, therefore, that she cannot understand some varieties of African-American speech, but isn't this because M and speakers of AAVE do not, as suggested earlier, share rule systems? Remember, M claims that she can't understand speakers of AAVE because they are 'lazy.' For her, the proof of this lies in the fact that many of them have not made any effort to learn her variety. She says, "I just don't think there's any excuse for it." What is 'it'? Of course, 'it' can only be the use of a variety that M cannot understand (at least within a social setting in which she believes she has the right to understand) or the failure to have learned her variety. It might appear at first that she simply believes that speakers cannot be excused for using their native-language rule-system when there is another one around preferred by some.

How can M justify her belief that those who do not acquire another rule system are 'lazy'? Isn't such acquisition difficult? In fact, we have already seen one reason many nonlinguists believe that standard English might be almost effortlessly acquired. As Figure 1 suggests, many find the standard variety to be the only embodiment of rule-governed behavior. The idea that nonstandard varieties are also rule governed is a very strange notion to the folk since nonstandard varieties are most often described by the folk as lacking rules. The relative ease with which speakers who have no rules should catch on to a rule-governed system (i.e., a grammar) appears to be obvious to speakers like M.

It would be inaccurate, therefore, to suggest that M's underlying belief was that people with different rule systems ought to acquire hers. In fact, her belief is that people who behave in non-rule-governed ways should make the minimal effort to acquire an orderly way of behaving.

This is, of course, a most serious linguistic misunderstanding. No matter what language system another person in the world shows up with, it is a system. And, equally important, for those who know its rule system, it is just as efficient a device for communication and/or the organization of thought as any other language system, as William Labov has shown so convincingly in 'The logic of nonstandard English' (1969). M's presupposition that nonstandard varieties have no rules, a fact clearly related to the predominant folk theory of language, at least in the United States, is the basis for much of her diatribe against speakers of African-American English.

There is, in addition, an alternative view of minority speakers that may cause even greater disparagement of such speakers than the 'lazy' accusation we have just seen. In this view, they are simply recalcitrant because they already know good English but just refuse to use it:

> J: And I used to teach Black children. And I had a difficult time understanding what they were saying. And I found out later though that they were – it was intentional, because they could speak – like we speak. And they wer- because: I – was having difficulty with this o(h)ne little bo(h) (h)y. He was twe(h)lve. (.hhh) And – I – was supposed to test him, for uh reading problems. And I couldn't understand what he was saying. And so I called uh the teacher next to me was Black. ( ) next to me. (.hhh) So I did go over and get her, and I asked if she would help me. (.hhh) And she came in and she- – just- said to him, she said 'You straighten up and talk – the right way. She's trying to help you.' (laughs)

M would be even angrier if she thought that all those people who were saying "Hey man, hybyayhuby-huby" could speak better but just refused to do so, but this is clearly what J has learned from her experience with a stubborn elementary school pupil (and she has been aided in this interpretation by a Black teacher, whom she regards as authoritative on the matter).

G, another schoolteacher, also voices the opinion that (apparently) all speakers know (somehow) the rules of standard English.

> G: The children themselves – all of us at time may say the improper endings. We may say it. (.hhh) But we recognize it is somebody says to us 'Is it correct,' you say 'No,' you know, 'This is the correct way (to) speak.' (.hhh) But- to sit and TEACH it incorrectly I don't think is right. Cause you DO say 'I have gone,' You do not say 'I have went.'

G seems to believe that nonstandard usage is somehow recognized by its speakers. Of course, to the extent that such speakers have been instructed in the details of the contrast between nonstandard and standard grammar or to the extent that they have constructed a contrastive grammatical analysis of their own on the basis of their exposure to both varieties, G may be in some small part right. But he appears to mean more than that. He appears to believe that there is some sort of innate recognition that nonstandard constructions are not right. Except for slips, then, which he recognizes, "there is no excuse" for the use of nonstandard varieties because we all know better.

Of course, that is not so. We do not know the rules of a variety we do not know. If you are a speaker of some standard variety of U.S. English, for example, try to imagine a situation in which everything you say or write will be judged and graded by how accurately it conforms to the rules of AAVE. After all, you have surely had a lot of exposure to it – from movies,

television programs, books, and even interpersonal communication. Most of us, however, would not fare very well. Among those who would get failing grades are those syndicated columnists in the United States (both Black and white, by the way) who wrote about the 1996–1997 Ebonics controversy, attempting to include examples of the variety. In fact, they performed miserably in AAVE. Most of their sentences would fall into the category 'not valid examples of the variety in question.' Their pathetic attempts were perfect illustrations of the pervasive folk belief that AAVE (or any nonstandard variety) consists merely of breaking the rules of standard English (any of its rules, any way one chooses to break them). (Admittedly, they seemed to use some silly strategy such as "sprinkle uninflected *be* widely throughout the discourse," but that is simply further proof that nonstandard varieties in the minds of the folk are not really rule governed.)

Whatever the viable folk linguistic notions turn out to be, such discourse research is fruitful in folk linguistics because it relies on established analytic procedures, in these cases on an analysis of the argument structure, one which outlined each position, support, and dispute as it arose, and on an analysis of presuppositions embedded in various discourses. These analyses allow situationally and culturally sensitive interpretations of the beliefs behind conversational content to be made. Folk linguistic investigations surely ought to involve further detailed analyses of talk about language, making use of the entire arsenal of discourse and conversation analytic tools now available to us.

Although perhaps most valuable in uncovering the dynamic instantiation of underlying folk belief about language, ethnographic observation and the analysis of folk discourses about language have not been the only methodologies employed. In the area of folk linguistics known as perceptual dialectology, for example, a number of quantitatively oriented collection methods have been employed. Respondents have drawn and labeled maps of regional speech, rated regions for such characteristics as correct and pleasant speech, identified the regional or other social (e.g., ethnic) provenience of speech samples, characterized the degree of difference between one speech region (usually their own) and others, and responded to experimental settings in which individual linguistic units have been manipulated (e.g., acoustically) to determine the degree of salience of specific features in triggering folk linguistic responses. Since the respondents in such research programs are fully aware of the linguistic nature of the tasks set before them (i.e., the identification or evaluation of speech regions or other groupings), this research for the most part seems to occupy the leftmost (b1) side of Figure 2. Further details of the program of research known as perceptual dialectology are provided in a separate entry (*see* **Perceptual Dialectology**), but much of that work illustrates the fact that quantitative as well as qualitative work has gone on in the folk linguistic research area.

Folk linguistic work has also been closely allied with the growing research program of sociophonetics. To take only one example, work in the perception of language increasingly focuses more specifically on the exact linguistic elements that give rise to perception rather than on the global presentation of varieties (or variety or area labels) in eliciting responses. Eliciting folk imitations is one way of approaching this problem (e.g., Evans, 2002; Preston, 1992, 1996a). The presentation of specific elements (by name, by actual sample, or by computer-modified samples) for identification, placement, and evaluation by respondents is perhaps an even better way to grasp greater details of the triggering mechanisms of language regard among the folk as well as the potential influence of such regard on the more general processes of variation and change. The lack of overt awareness by the respondents of the elements being manipulated in such research, however, brings us away from the b1 corner.

For example, when Graff, Labov, and Harris (1986) instrumentally manipulated the onset of the /aw/ diphthong of an African-American speaker from Philadelphia (in which the /a/ portion was synthetically fronted to a position nearer /æ/), they succeeded in showing that this fronting alone (with no other alteration of the speaker's performance) was enough to signal white ethnicity to both African- and European-American local respondents. They suggested that such acoustic modification and presentation was a new tool for sociolinguistic research. If ethnic identification by language cues alone is a folk ability, then such research as this surely qualifies as folk linguistics.

Folk linguistics may also work hand in hand with investigations of much finer details, perhaps even those approaching the bn corner. For example, Niedzielski (1999) studied the local Detroit awareness of 'Canadian raising,' in which the onsets of the /aw/ ('house') and /ay/ ('night') diphthongs are raised before voiceless consonants. She played a Detroit female speaker's pronunciation of the word 'house' in which the onset of /aw/ was considerably raised. Although Detroiters associate this pronunciation with Canadians, they quite regularly perform it themselves. She asked Detroit respondents to match this vowel with one of three others (synthesized tokens), which they had heard several times. The first (#2 in Table 1) is called 'ultra-low' since it represented an

Table 1 Influence of nationality labels on token selection (for 'house')[a]

Token label	*#2*	*#3 Canonical /a/*	*#4 Actual token*	*Total*
CANADIAN	15%	25%	60%	
	n = 6	10	24	40
MICHIGAN	38%	51%	11%	
	n = 15	20	4	39

[a]Chi-square = 23.48; $p < .001$; Source: Niedzielski, 1999.

onset considerably below the norm (for F1) for /a/ in local speech. The second is called 'canonical' /a/ and represented the height of /a/ as given in Peterson and Barney (1952), an acoustic study of so-called General American vowels. The third token to which the sample was to be matched is called 'actual' and was the same token used in the sample itself, one in which the onset was considerably raised. Respondents heard these tokens mixed with others, but the presentation was significantly different for two groups; one received an answer sheet which had the word 'CANADIAN' prominently printed at the top of the page; the second received an answer sheet with the word 'MICHIGAN' at the top. Any difference in token matching by the two groups, therefore, can be attributed to that apparent regional identification.

As Table 1 shows, labeling had a strong effect. Sixty percent of the 40 respondents who had the word 'CANADIAN' printed on their response sheets matched the token presented with the 'actual' one (i.e., accurately), in contrast to only 11% of the 39 who had sheets with 'MICHIGAN' written on them. Fully 51% of the respondents with the 'MICHIGAN' written cue heard the token as 'canonical /a/,' and 38% even heard it as 'ultra-low.' It is obvious that the identification of the home site of the sample voice exerted an enormous effect on the sound that was heard by the respondents.

How do the results of this experiment fit requirements for folk linguistic investigation, presumably ones nearer the b1 corner of Figure 2? First, although Detroit-area respondents are fully aware of Canadian Raising (an a-corner fact), they do not imitate it correctly (they say [hus] instead of [hʌws]). So they have a b1-corner consciousness of an 'a' phenomenon, but an inaccurate one, and folk facts are already at work. Second, they apparently unconsciously (somewhere closer to bn) bring the regional information supplied to them on their answer sheets to bear on an 'a' fact – the similarity of two vowel sounds. Recall that the voice they hear is identified as being from Michigan or from Canada, when it is in fact always the same voice. Finally, and most interestingly, how does the awareness of region b1 cause such inaccuracy in characterizing 'a'? The b′ information is not hard to locate in this case.

A dominating concern among U.S. folk respondents is with prescription, and Michiganders regard themselves as the best speakers in the United States (e.g., Preston, 1996b), residents of the mythic heartland, where no dialect is spoken. The folk imposition on vowel perception is, therefore, easy to understand. If Michiganders are speakers of standard English, then the most standard-like vowel is the one the Michigan speaker pronounced, regardless of acoustic reality. The deeper folk theory (b′) of the standard language and the shallower b′ belief that Michigan speakers lie very close to that standard triggers an automatic classification of likely behavior (bn) when Michigan respondents are asked to carry out a vowel-matching task based on regional identity (b1).

The empowering folk beliefs of b′, the ultimate goal in the quest for an understanding of folk linguistics, not only influence the conscious and unconscious reflections on and reactions to language that are a part of the continuum at the base of the triangle but also interact with the perception of language data itself, the very stuff of 'a.' This suggests that any linguistics without folk linguistics does not explore the breadth and depth of language in communities – the regard in which it is held and even the ways in which it is processed and eventually modified in the progress of language change.

In conclusion, the study of folk beliefs about language may be recommended for at least four reasons:

First, it is simply one of the ethnographies that one might choose to do of a culture. In ethnobotany one wants to learn (at least) a culture's beliefs about the naming of, relationships among, and uses for plants. Ethnolinguistics should do the same for language, but the contrast between a folk and a scientific linguistics will be more complex than that between many other ethnosciences and their academic partners, particularly in a nonhomogeneous, late-modern society.

The role of language and its attendant beliefs ought to be set in the larger framework of the culture under investigation, for ethnolinguistics may not be just more complex than ethnobotany or ethnogeology but more complex in subtle ways. If it is believed (and reported) that a certain plant is good for settling the stomach, it would be odd to find it seldom used for that purpose (unless some taboo restricted its use). A contrast between belief and use in language, however, is not at all an uncommon state of affairs ("I know what's right, but I don't talk that way"); this apparent mismatch requires greater subtlety in combining ethnolinguistics with a study of language

in use. All the work done in the area of folk linguistic enquiry contributes to this goal of the larger understanding of language as a cultural tool.

Second, for those who want to employ solutions that linguistics may offer to real-world problems, there is surely no more important information the applied linguist can have than that of the authentic folk belief about language held by those with whom he or she would work. Imagine a rural doctor who did not know that 'the sugar' was the local term for diabetes! Here is a concrete folk linguistic example. In work on the contrast between language teacher and language student beliefs about language acquisition, Peacock (1998) showed that error correction by the teacher was valued very highly by the pupils and hardly at all by the teacher. One can imagine that an underlying folk theory held by the learners is that uncorrected errors lead to bad habits, a position not likely to be held by the teachers, particularly those who have been trained by modern linguists, who reject a theory of habit-formation, and modern language teacher trainers, who favor a so-called communicative approach. The latter is particularly tolerant of student errors, especially during activities in which students are supposed to gain communicative control of the language and for which self-assurance is seen as beneficial. In short, a modern communicatively oriented language teaching program would surely rub the folk in such a community the wrong way, and not to know that in advance would preclude any preparatory work that administrators, curriculum designers, textbook writers, and teachers might do.

Third, since the folk are in constant contact with language and varieties, might it be the case that they can provide clues to interesting linguistic features that have not been focused on by linguists? In a recent investigation of the vowels involved in a dramatic change in the urban north of the United States, Plichta (2004) discovered that several of these vowels have added a strong nasal component, even when there is no nasal consonant present. This is certainly not an odd finding; nasal vowels outside of nasal environments are common, but this discovery is perhaps many years late due to the ignoring of folk linguistic evidence. For some time it has been known that upper Midwestern speakers of U.S. English have been regarded as nasal by speakers from other areas. This had been universally disregarded by dialectologists and sociolinguists, who assumed that the folk simply associated certain vowel changes with a nasal vocal quality that was not there. Labov, in his comments on Hoenigswald's 1964 presentation on folk linguistics, noted that nasalization was one of the facts that folk observers had no accurate perception of at all, for they reported that both nasalized and denasalized speech examples are nasal. Plichta's work showed, however, that speakers of the dialect in question were, in fact, nasalizing certain segments, and the folk perception of that fact had been available to researchers for some time.

Fourth, and perhaps most important (at least so far as linguists are concerned), folk linguistic beliefs may help determine the shape of a language itself. It would be unusual to discover that what nonlinguists believe about language has nothing to do with the strengthening or weakening of targets in linguistic change. It is obvious, for example, that the underlying ideology of correctness or a folk belief in language standards influences grammatical selection and, therefore, the establishment of constructions. In Albanyan and Preston (1998), for example, it was shown that undergraduate students at a large U.S. Midwestern university were worried that the prescriptively sanctioned *they gave the bill to Carol and me* might be wrong. They were worried, of course, because they had doubtless been criticized by teachers, parents, and others for using such expressions in subject position (e.g., *Carol and me wanted the bill*) and had now extended their fear to other cases. Almost 10% of the students surveyed said that they would prefer *they gave the bill to Carol and myself* on all occasions, and 21% said they liked that construction best for formal writing and speech. Another 20% said they preferred *they gave the bill to Carol and I* for all occasions. It is clear that a concern for language correctness has, at least in part, disrupted the historical distribution of nominative, oblique, and reflexive pronouns in U.S. English. Doubtless many other winners and losers in the ebb and flow of language can be best accounted for with reference to linguistic folk belief.

Even if these relations of folk linguistics to central concerns in language description and change do not obtain, the first two goals would be sufficient, at least within a linguistics broadly conceived, to earn folk linguistics an important place.

Finally, it is helpful to recall that the study of folk behavior should be done with regard to its dynamic as well as static nature. In a modern folk linguistics, it will be important to observe the routes folk follow in thinking through problems about language as well as their prepackaged items and conventional structures of belief, whatever role these latter may play in more active processes. For example, it is important to know that in English, *still waters run deep* is a folk saying that suggests that those who don't speak much may be wise, but a more thorough investigation of folk linguistics in its dynamic sense would seek out its actual deployment, not just cite the fact that it is a fixed folk linguistic phrase.

In addition, like other studies in the ethnography of speaking, a responsible folk linguistics should seek the organizing principles behind belief, and some parts of this brief account have illustrated such attempts. Folk linguistics is, however, not the only rubric under which such investigations have been carried out. Linguistic anthropologists have, for some time, been concerned with the investigation of cultural behaviors and the models that underlie them; such behaviors clearly include language. Recent work on language ideology would seem to come most directly from this tradition (e.g., Woolard and Schieffelin, 1994), and a facile division of labor might suggest that folk linguistics is concerned with the leftmost side of Figure 2 (b1), language attitudes with the rightmost side (bn), and language ideology with underlying principles, theories, and beliefs about language and those related areas that influence beliefs about language (b′). That is a tempting subdivision of labor, but it would leave the areas of language attitude study (perhaps the entire social psychology of language) and folk linguistics as purely descriptive modes of research, never reaching to the explanatory level. At the present time, it seems premature to suggest any definitive description of these subdisciplinary boundaries.

The intellectual debt in both the folk linguistic and language ideology enterprises, however, is surely greatest to those ethnographers of speaking whose work with a variety of data from a variety of contexts leads to an enriched understanding of language. Hymes puts it simply and directly:

> If the community's own theory of linguistic repertoire and speech is considered (as it must be in any serious ethnographic account), matters become all the more complex and interesting. (Hymes, 1972: 39)

If we allow a space in linguistics for a development of the understanding of ordinary speakers' metalinguistics (as well as their competence, performance, and reaction), we will surely come even closer to realizing the full account of language we seek. By doing so we may also succeed, in one more way, in making our science relevant to the human needs around us.

Food: Semiotics

M Danesi, University of Toronto, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

In cultural settings, different types of food, culinary preparations, eating events and rituals, and food-celebrating occasions are signs and texts that are part of a culture's overarching network of meanings. The eating of meat, for example, is dependent upon the specific connotations that a certain animal has in that network. In Western society, eating beef is a common occurrence, no matter what form its preparation takes (steak, hamburger, etc.), because cattle meat is perceived as an edible food, whereas the eating of rabbit or cat meat is not, for the reason that the animals in this case are defined culturally as domestic companions. As this simple illustration indicates, meat is a sign that derives its meanings from the network of culture-specific meanings that animals possess. In most meat-eating societies, certain animals are identified as sources of food, others are not, rendering them 'uneatable.'

Food is clearly much more than substance for nourishment and sustenance. It is part of a sign system imbued with culture-specific connotations. As such, it is studied by both anthropologists (e.g., Goody, 1982; Goode, 1992; Mintz, 1996; Schlosser, 2000) and semioticians, starting with Claude Lévi-Strauss's brilliant 1964 essay on the semiotic difference between 'raw' and 'cooked' food, in which he argued that cooked meals were the foundation of various religious and social practices. Many Christians, for instance, say grace before starting a meal together; Jews say special prayers before partaking of wine and bread. At a formal meal, the order in which dishes are presented, what combinations can be served in tandem, how the foods are to be placed on the table, who has preference in being served, who must show deference, who does the speaking and who the listening, who sits where, and what topics of conversation are appropriate are all based on traditions derived from cooking food. All cultures, moreover, have a discrete set of table rituals and manners accompanying the cooking of food that are inculcated into the members of the culture from birth. If one does not know the table-manner code, then he or she will have

Food: Semiotics

M Danesi, University of Toronto, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

In cultural settings, different types of food, culinary preparations, eating events and rituals, and food-celebrating occasions are signs and texts that are part of a culture's overarching network of meanings. The eating of meat, for example, is dependent upon the specific connotations that a certain animal has in that network. In Western society, eating beef is a common occurrence, no matter what form its preparation takes (steak, hamburger, etc.), because cattle meat is perceived as an edible food, whereas the eating of rabbit or cat meat is not, for the reason that the animals in this case are defined culturally as domestic companions. As this simple illustration indicates, meat is a sign that derives its meanings from the network of culture-specific meanings that animals possess. In most meat-eating societies, certain animals are identified as sources of food, others are not, rendering them 'uneatable.'

Food is clearly much more than substance for nourishment and sustenance. It is part of a sign system imbued with culture-specific connotations. As such, it is studied by both anthropologists (e.g., Goody, 1982; Goode, 1992; Mintz, 1996; Schlosser, 2000) and semioticians, starting with Claude Lévi-Strauss's brilliant 1964 essay on the semiotic difference between 'raw' and 'cooked' food, in which he argued that cooked meals were the foundation of various religious and social practices. Many Christians, for instance, say grace before starting a meal together; Jews say special prayers before partaking of wine and bread. At a formal meal, the order in which dishes are presented, what combinations can be served in tandem, how the foods are to be placed on the table, who has preference in being served, who must show deference, who does the speaking and who the listening, who sits where, and what topics of conversation are appropriate are all based on traditions derived from cooking food. All cultures, moreover, have a discrete set of table rituals and manners accompanying the cooking of food that are inculcated into the members of the culture from birth. If one does not know the table-manner code, then he or she will have

to learn it in order to continue living in the culture without censure and disapprobation.

The social importance of food was noted first in writing by the Greek historian Herodotus (c. 484–425 BCE), who spent a large part of his life traveling through Asia, Babylon, Egypt, and Greece, noting and recording for posterity the differences he perceived (with respect to Athenian culture) in the language, dress, food, etiquette, legends, and rituals of the different people he came across. The annotations he made constitute the first significant accounts of the cultures of virtually the entire ancient Middle East, including those of the Scythians, Medes, Persians, Assyrians, and Egyptians. Inspired by Herodotus, other ancient historians also made it a point to describe systematically and comparatively the languages, character, manners, and geographical distribution of the peoples they visited. As these ancient 'anthropologists' discovered, in a social ambiance food takes on significance that transcends its basic survival function, affecting perceptions of its edibility. Food mirrors social organization, religious beliefs, and other aspects of communal life. It is, in other words, an important element for understanding the overall 'code' of a culture.

Systems of 'etiquette,' incidentally, existed even in early tribal settings. As prehistoric people began to interact with one another, they learned to behave in ways that made life easier and more pleasant. For example, as people learned to plant crops and farm, the ability to store food led to communal eating. Rituals developed for the preparation and sharing of meals which, over time, evolved into the table manners of today. Then, early civilizations, such as those of ancient Greece and Rome, developed rules for proper social conduct. Such rules became more formal during the Middle Ages, during which boys training to become knights learned a code of conduct called 'chivalry.' According to this code, a knight was devoted to the Christian church and his country and treated women with great respect. Some aspects of chivalry, particularly the special treatment of women, became a traditional part of manners.

Much of today's formal etiquette originated in the French royal courts during the 1600s and 1700s. King Louis XIV drew up a daily list of events, giving time, place, and proper dress. It was posted in his palace at Versailles as an etiquette, a French word meaning ticket, to help the nobles know what to do. It brought order to court society, and other monarchs adopted the code of behavior for their own courts. In time, upper classes throughout the Western world adopted the code.

Food vs. Cuisine

Of course, survival without food is impossible. So, denotatively, food can be defined as 'survival substance.' But, in a social ambiance, food and eating involve the enactment of culture-specific connotations. The term that is often used to designate the system of connotations that food evokes is 'cuisine.' Cuisine informs us not only as to what certain people eat, but also how they make it, and ultimately what it reveals about them.

The earliest people probably ate whatever plant food they could find, including fruits, mushrooms, nuts, roots, and seeds. They also caught fish and small land animals, and ate the meat of the dead animals they found. In time, they developed weapons to hunt large animals, and probably spent much time searching for them. If the food supply in an area ran out, they apparently moved on. They roasted some of their food over burning wood from fires that started naturally. After they discovered how to make fire, they started roasting food more often. After they learned how to make pots, they began boiling and stewing food.

By about 8000 BCE, people began raising plants and animals for food – hence the rise of farming as a communal activity, assuring people of a steadier food supply. It also meant settling in one area instead of traveling about in search of food. Grains were especially important crops for the early farming communities. So was the raising of cattle, goats, sheep, and other animals for meat and milk. Some groups of prehistoric people were nomadic. They traveled across the countryside in patterns, raising such animals as camels, goats, and sheep. Between 3500 and 1500 BCE, the first great civilizations developed in river valleys, such as the Nile Valley in Egypt, the Tigris-Euphrates Valley in what is now Iraq, the Indus Valley in what are now Pakistan and northwestern India, and the Huang He Valley in China. All these valleys had fertile soil and a favorable climate, which enabled farmers to produce abundant yields. In ancient Egypt, for example, farmers along the Nile could raise two or three crops a year on the same fields. They grew barley and wheat and such vegetables as beans, lettuce, and peas. The Egyptians also cultivated such fruits as grapes and melons. Their livestock also included cattle, goats, and sheep.

At first, the ancient Greek and Roman societies could not produce enough food for their growing populations. They thus had to import large quantities of food from other countries. This may be the reason why both civilizations took the decision to conquer

and colonize lands that had plentiful food supplies. By the 3rd century AD, the Roman Empire covered much of Europe, most of the Middle East, and the Mediterranean coast of Africa. Most of the empire's large farms specialized in raising wheat, which formed the basis of the Roman diet.

The origin of true culture is, arguably, the result of efforts to secure a source of food and to invent a technology to make the provision of food abundant and stable. As mentioned, the anthropologist Claude Lévi-Strauss (1964) argued that the origin of culture can, in fact, be traced to the advent of 'cooking technology.' Lévi-Strauss claimed that this transformation was accomplished by two processes – roasting and boiling – both of which were among the first significant technological advances made by humanity. Roasting is more primitive than boiling because it implies a direct contact between the food and a fire. But boiling reveals an advanced form of technology, because the process in this case is mediated by a pot. Boiling was the event that led to the institution of true culture – which implies the sharing of food in the community of others. At that point, food took on symbolic meanings.

To grasp how this may have come about, it is useful to imagine being in a 'Robinson Crusoe' situation – Robinson Crusoe being the protagonist in Daniel Defoe's (1660?–1731) famous novel, *The life and adventures of Robinson Crusoe*, which appeared in 1719. Although the novel is the fictional tale of a shipwrecked sailor, it is nonetheless based on the real adventures of a seaman, Alexander Selkirk (1676–1721), who had been marooned on an island off the coast of Chile. The novel chronicles Crusoe's ingenious attempts to overcome the hardships he faces on the island. Like Robinson Crusoe, one can imagine being abandoned on an isolated island in the middle of nowhere. Without the support and security of a social ambiance, our first instincts are to survive in any way that we can. In such a situation, the need for food and water takes precedence over all else. One would hardly tend to be fussy about what to eat. In effect, we would eat whatever we find.

Now, suppose that after living alone on the island for a few years we discover other similarly abandoned individuals, each one on some remote part of the island, all of whom speak the same language. Since there is strength in numbers, the decision is made by all concerned to become a group, in which specific roles are assigned to each person for the procurement, storage, and preparation of food. This division of labor constitutes an emergent 'social contract.' As time passes, other 'social contracts' are made, all designed to ensure survival. The food eaten and its method of preparation will start at that point in time to take on meanings that transcend survival. The group may want, for instance, to reserve a day of the week to eat a special type of food, cooked in a special way, to symbolize the gratitude each one feels (for having survived). From this a rudimentary religious tradition can be established. Other traditions can also be similarly instituted.

This vignette suggests that food cooked for a community of eaters is bound to take on significance beyond that of 'survival substance.' When especially abundant food sources became available, early humans settled in permanent, year-round communities, learning to domesticate plants and animals for food, transportation, clothing, and other uses. With greater population concentrations and permanent living sites, social contracts evolved into cultural institutions complemented by religious ceremonies and ritualistic food events (such as communal meals and feasts). These early hunting-gathering societies soon developed complex belief systems with regard to the supernatural world, and the behaviors of spirits and gods. Food became a part of ritual and communal meaning-sharing, often offered to the deities in return for specific favors. To this day, food is perceived invariably as a primary constituent of all kinds of ceremonies and rituals, from feasts (weddings, Bar Mitzvahs, etc.) to simple social gatherings. We schedule 'breakfast,' 'lunch,' and 'dinner' events on a daily basis. Indeed, we plan our days around meals. Even going out on a common romantic date would be virtually unthinkable without some eating component associated with this courtship ritual (ranging from the popcorn eaten at movie theaters to the elaborate meals consumed at trendy restaurants).

Food as Symbolism

As part of rituals, food items take on symbolic meanings. Take, for example, bread. We talk of the 'bread of life,' of 'earning one's bread,' and so on because, as in many other cultures, bread is a symbol for life. The word 'companion', incidentally, comes from Latin and means literally the person 'with whom we share bread'. As Margaret Visser (1991: 2–3) aptly pointed out:

> This is true even in our own day, when people eat far less bread than they used to, and when bread comes to us from a factory, bleached, squishy, ready-cut (so much for 'breaking bread'), wrapped in plastic or cellophane. Yet we still expect to have bread on hand at every meal, as background, as completion, as dependable comforter and

> recompense for any stress or disappointment the rest of the meal might occasion. Bread is for us a kind of successor to the motherly breast, and it has been over the centuries responsible for billions of sighs of satisfaction.

The probable reason for the association of bread with life may be the fact that it is one of the oldest foods eaten and prepared by humans. Prehistoric people made flat bread by mixing grain meal with water and baking the resulting dough on rocks that they had heated. Historians believe the Egyptians learned to make yeast bread around 2600 B.C. The ancient Greeks learned bread-making from the Egyptians and later taught the Romans how to do it. By the 1st century A.D., the Romans passed this knowledge on to the people in the many parts of Europe they had conquered.

Many of the symbolic meanings of food derive from accounts of human origins. The story of Adam and Eve in the Western Bible, for instance, revolves around the eating of a forbidden fruit. The representation of this fruit as an apple came in medieval pictorial representations of the Eden scene. Since then, the Biblical symbolism of the apple as 'forbidden knowledge' continues to resonate across many societies. This is why the apple tree symbolizes the 'tree of knowledge;' why the 'Apple' computer company has probably chosen this fruit for its company name and logo, and so on. The discovery and cultivation of the apple dates back to 6500 B.C. in Asia Minor. Ramses II of Egypt cultivated apples in orchards along the Nile in the 13th century B.C. The Ancient Greeks also grew apple trees from the 7th century B.C. onward. They designated the apple 'the golden fruit,' since in Greek mythology the apple was given to Hera from the Garden of the Hesperides as a wedding present when she married Zeus.

As another example of food symbolism, consider lamb meat. This is a particularly important Easter food in central and eastern European countries. It is eaten at this time period of the liturgical year because it represents Jesus and relates His death to that of the lamb sacrificed on the first Passover. This is why Christians traditionally refer to Jesus as 'the Lamb of God.' In many homes, a lamb-shaped cake also decorates the table at Easter. Many Eastern Orthodox Christians even hang pictures of the Easter lamb in their homes.

Similar accounts as those above can be sketched for virtually any of the traditional foods we continue to eat today. Symbolism is also the reason why the meat of certain animals is not eaten by certain people. And it is also the reason for fasting. Fasting is one of a number of rites in which physical activities are reduced or suspended, resulting in a state of quiescence symbolically comparable to death, or to the state preceding birth. Fasts have been part of fertility rites since pre-historic times.

In addition to fasting so as to induce fertility, there are fasts intended to avert catastrophe or to serve as penance for sin. The ancient Assyrians and the Babylonians observed fasts as a form of penance. Among Jews, too, fasting has always signified penitence and purification. This is why fasting is observed annually on the Day of Atonement, Yom Kippur. The fast observed by Muslims during the month of Ramadan is another expression of atonement. Although most Protestant churches retained fasting after the Reformation in the 16th century, stricter Protestants such as the Puritans condemned traditional fasts. The Orthodox Church, on the other hand, continues to observe fasts rigorously. Native North Americans hold tribal fasts to avert impending disasters. Political fasting, known as 'hunger striking' has also been employed as a political weapon ever since Mohandas Gandhi, leader of the struggle for India's freedom, used it effectively in the early and mid-1900s.

The counterpart to fasting is overeating. One tradition based on culinary indulgence is 'carnival,' which in Christian cultures consists of feasting and merrymaking just before Lent. The Mardi Gras in New Orleans is a famous American carnival. From this religious tradition the modern concept of a carnival as a form of outdoor amusement that consists of exhibits, games, rides, shows, and all kinds of tempting foods gradually developed.

The Edible and the Non-edible

Eating foods constitutes an act of 'sign-eating.' This can be seen when someone is asked to eat something perceived semiotically as inedible. In Anglo-American culture that is the case of rabbits, which are defined as 'household companions' rather than as sources of food. The same culture also does not classify foxes or dogs as edible food items; but the former is reckoned a delicacy in Russia, and the latter a delicacy in China. On the other hand, bovine meat (beef steaks, hamburgers, etc.), lamb meat, and poultry meat are eaten routinely in Anglo-American and European culture, with few negative perceptions and gustatory reactions. In India, on the other hand, a cow is considered by religious tradition to be sacred and, therefore, beef is perceived to be inedible.

It is interesting to note that, historically, the ancient Romans were the ones who had domesticated the rabbit, which flourished throughout their empire as a source of food. In 16th-century England, rabbits were prized instead for their fur. For this reason,

they were bred selectively in order to enhance their rich coats. In the 19th century, England passed strict game laws prohibiting rabbit hunting. In the remainder of the previous Roman empire, however, they continued to be perceived as food sources. By the turn of the 20th century, rabbits were redefined in Anglo-American culture as household animals. The reinforcement of the anthropomorphic connotations that the rabbit has since taken on can be seen in the popularity of fictional rabbit characters ('Bugs Bunny,' the 'Easter Bunny,' 'Benjamin Bunny') that have become a part of childhood.

Edibility is, in sum, more a product of Culture than of Nature. Outside of those that have a demonstrably harmful effect on the human organism, the species of flora and fauna that are considered to be edible or inedible are very much the result of history and tradition. We cannot get nourishment from eating tree bark, grass, or straw. But we certainly could get it from eating frogs, ants, earthworms, silkworms, lizards, and snails. Most people in Anglo-American culture would, however, respond with disgust at the thought of eating such potential food items. However, there are cultures where they are not only eaten for nourishment, but also as part of symbolic traditions. The expression 'to develop a taste' for some 'foreign' food reveals how closely tied edibility is to cultural perception. Left alone on that hypothetical Robinson Crusoe island described above, the question would certainly not be one of 'taste,' but of 'survival' at any taste.

So close is the association between food and culture that it is used commonly and stereotypically as a template for evaluating other people and their cultures. People perceive gustatory differences in cuisine as fundamental differences in worldview and lifestyle – as differences between 'us' and 'them.' It is relevant to note that when people come to accept the cuisine of others as not only tasty but as a delicacy, the culture of the food-makers concomitantly is perceived much more positively.

Food Codes

Food codes, like all other kinds of social codes, are regulatory systems – they control what kinds of food are eaten, when they are eaten, who is allowed to eat them, and so on and so forth. Predictably, these vary considerably from culture to culture, having an effect on how certain foods are perceived, on how they are prepared, on who has priority in eating them, and so on (Goode, 1992: 236–245). Here are a few examples:

1. The adult !Kung Bushmen of the Kalahari Desert in southern Africa never eat the scavenged contents of a bird's nest, but will use it to make soup for their children.
2. In traditional Chinese households, the eldest eats first, followed by the next generation, on down to the youngest.
3. At certain intervals, the richest members of the Kwakiutl society of the Pacific Northwest put on a lavish feast during which they give away material gifts as a sign of bonding with all the members of the society.
4. At matrimonial ceremonies throughout the world, specific kinds of codes may dictate the organization of parts of the ceremony (e.g., the wedding party normally sits apart from the invited guests).

Above all else, food codes dictate how eating events are organized, including: the order in which dishes are presented; what combinations can be served in tandem; how the foods are to be placed on the table; who has preference in being served; who must show deference; who does the speaking and who the listening; who sits where; what topics of conversation are appropriate. As Visser (1991: 107) remarked, "dinner invitations can be fraught with hope and danger, and dinner parties are dramatic events at which decisions can be made and important relationships initiated, tested, or broken."

Eating events are so crucial to the establishment and maintenance of social relations and harmony that there exists virtually no culture that does not assign an area of the domestic abode to eating functions and ceremonies. All cultures, moreover, have a discrete set of table rituals and manners that are inculcated into the members of the culture from birth. If you do not know the table-manner code of a certain culture, then you will have to learn it in order to continue living in that culture without reproach and disapproval. Consider a concrete example. If you have never eaten spaghetti before, then you will have to learn that the 'correct' way is to eat it with a fork if you find yourself in Italy. In 19th-century Naples, where the modern-day version of this dish comes from, people ate spaghetti with their hands by raising each string of pasta in the hand, throwing back the head, and lowering the string into the mouth without slurping. Today, the correct manner of eating spaghetti is to twirl it around the fork, in small doses, and then to insert the fork into the mouth as one does with any other fork-based intake of food. Eating spaghetti in any other way would be perceived as a breach of the relevant table-manner code.

Table-manner codes often involve the use of flatware. Knives, spoons, forks, and other specialized implements for eating and serving food have until recent times been the privilege of the aristocracy. In Egypt, Greece, and Rome knives and spoons of the aristocracy were made of precious materials, including silver and gold, and were sometimes decorated. The Romans also possessed skewers. These were forerunners of forks. From the Middle Ages until the Renaissance, the knife remained the principal table utensil. Forks came into common table use in Italy in the 1500s. At the same time, spoons made the transition from kitchen utensils to table flatware. From that time onward, flatware came to be used by all peoples of all classes. During the 19th century, numerous other items of flatware were created, such as teaspoons, butter knives, and salad forks.

Semioticians typically view food codes as prototypical social codes (Parmentier, 1994; Gottdiener, 1995). The signs that we use to make messages are not randomly chosen structures. When we enter into an eating event, for example, we will be able to participate successfully in it only if we know the appropriate food code. This provides information about specifics of how to eat food, when to speak during eating, and so on. Food codes tend to be more or less stable and fixed, varying very little over time, if at all. But they are adaptive nonetheless. And, like all codes, they are sensitive to context. Eating a wiener with the hands would be inappropriate in a high-class restaurant, but it would be one of the ways to eat it at an open-air meal among friends at a barbecue where cutlery may not be available. Clearly, the physical context of occurrence and social frame of reference will determine how a food item is eaten. The restaurant is, itself, a social code. This is why we interpret anything that is eaten there differently than if it is eaten somewhere else.

The network of interconnected meanings that constitute a culture is configured with such social codes. These can be characterized as 'organizational grids' within the network. Utilization of these codes for various interactive reasons will, of course, vary, but the basic structure of the codes will remain intact and recognizable.

Conclusion

The semiotic investigation of food illustrates how Nature and Culture intersect constantly in human life. At a denotative level, food means exactly what Nature has decreed it to mean – survival substance. However, in cultural settings, food items become signs that assume specific kinds of meanings. And these cohere into codes that govern how they are evaluated and eaten. Cultures vary widely as to the types and the degree of meaning they assign to food and eating. But throughout the world, food is viewed to be as much symbolic substance as it is survival substance.

Foot

B Alber, University of Verona, Verona, Italy

© 2006 Elsevier Ltd. All rights reserved.

The Foot as a Metrical Unit

The foot is the basic unit of word stress assignment in many contemporary linguistic theories. Theories making use of the concept of foot thus maintain that word stress is a property not of single segments or syllables but of groups of syllables, i.e., feet (see Kenstowicz, 1994; Hayes, 1995; Kager, 1995, for an overview on the role of the foot in metrical theory).

It is generally assumed that in the prosodic hierarchy (Selkirk, 1980) the foot occupies the position above the level of the syllable and below the prosodic word level. One or more syllables form a foot, and one or more feet, in turn, the prosodic word:

```
(1)    ... Prosodic word ...
                  |
             ... Foot ...
                / \
     ... Syllable    Syllable ...
```

Analysts diverge as to whether they assume that syllables have to be parsed exhaustively into feet (e.g., Halle and Vergnaud, 1987) or whether they maintain that natural language allows syllables to remain unfooted (Prince, 1983; McCarthy and Prince, 1993; Hayes, 1995, among others).

Metrical units have been used under various names for the description of stress patterns at least since Scott (1948), Miyaoka (1971), Lehiste (1965), Allen (1973) (see Hayes, 1995, for an overview). In generative grammar, Liberman (1975) introduced the idea of metrical constituents and Prince (1976a, 1976b) first proposed stress assignment as the direct construction of constituents. The name 'foot,' borrowed from poetic meter, has established itself through the work by Selkirk (1980).

The foot has since been employed first of all to describe the rhythmic structure of words and phenomena determined by it, such as main stress and rhythmical secondary stress. Take, for instance, Seminole/Creek (McCarthy, 1979; Hayes, 1995; data from Haas, 1977, and Tyhurst, 1987). In a string of light syllables (heavy syllables are abstracted away from, here), a high tone falls either on the penult or on the final syllable of the word, whichever is preceded by an odd number of syllables. If we employ the concept of foot, we can simplify this description and say that in Seminole/Creek iambic (i.e., right-headed) feet are parsed beginning at the left edge of the word, grouping always two light syllables into a foot. A high pitch accent is then assigned to the head of the last foot generated by this parsing, as we can see in (2). In the examples, foot boundaries are indicated with round brackets; L stands for a light syllable, H for a heavy syllable, and *σ* for a syllable in general, in languages in which syllable weight does not play any role in stress assignment (see the discussion of quantity-sensitive and quantity-insensitive systems). An acute accent [´] generally indicates main stress (in the Seminole/Creek examples below it indicates high tone) and grave accent [`] secondary stress.

(2) a.	cokó (LĹ)	'house'
b.	osána (LĹ)L	'otter'
c.	apataká (LL) (LĹ)	'pancake'
d.	anokicíta (LL) (LĹ)L	'to love'
e.	isimahicitá (LL) (LL) (LĹ)	'one to sight at one'
f.	itiwanayipíta (LL) (LL) (LĹ)L	'to tie each other'

Wargamay (Dixon, 1981; Hayes, 1995) is a language with the opposite directionality in metrical parsing. In strings of light syllables, main stress is assigned to the first syllable in even-numbered strings and to the second syllable in odd-numbered strings. If we describe the pattern making use of the concept of foot, it becomes clear why the even or odd number of syllables should make a difference: trochaic (i.e., left-headed) feet are parsed from right to left and main stress is assigned to the leftmost foot generated by this parsing.

(3)	báda (*σ́σ*)	'dog'
	gagára *σ*(*σ́σ*)	'dilly bag'
	gíɲawùlu (*σ́σ*)(*σ̀σ*)	'freshwater jewfish'
	ɲuɽágay- mìri *σ*(*σ́σ*)(*σ̀σ*)	'Niagara-Vale-FROM'

Thus, in metrical theories, directionality of secondary stress is traditionally expressed indicating the direction of parsing of secondary stress feet: feet are parsed either starting from the left edge of the word proceding to the right, as in Seminole/Creek, or starting at the right edge proceeding leftward, as in Wargamay.

Since McCarthy and Prince (1993a), the directionality of secondary stress feet is also described as alignment of feet to the left or the right edge of the prosodic word. Seminole/Creek aligns feet as

much as possible to the left edge of the word, whereas Wargamay aligns them as much as possible to the right.

In the next section, the state of the art regarding the shapes that feet can take will be summarized. In the final section of the article, the most important arguments that have been brought forward for the existence of the category foot will be discussed.

Parameters Determining the Shape of Feet

For various theories on the parameters determining metrical patterns and hence also foot-shape, see Liberman and Prince (1977), Halle and Vergnaud (1978, 1987), Hayes (1981, 1995), Prince (1983, 1990), Idsardi (1992), McCarthy and Prince (1993), Prince and Smolensky (1993), Kager (1993a, 1995), Halle and Idsardi (1995), and Hyde (2002).

Quantity-sensitive and Quantity-Insensitive Feet

So-called quantity-sensitive languages distinguish between heavy and light syllables, whereas in quantity-insensitive languages for the purpose of stress assignment all syllables count as light (see Kager, 1992, 1993a, 1993b, for the distinction between *trivially* and *truly* quantity-insensitive systems, i.e., systems that do not have any weight-contrast between syllables in general and systems that do have a contrast but where weight does not influence stress placement). In quantity-sensitive languages, syllables containing long vowels or diphthongs, and, in many languages, also syllables closed in a consonant, count as heavy. The difference between heavy and light syllables is often represented by assigning to the rhyme of heavy syllables two 'weight-units,' called moras (μ), and to light syllables only one. The moras are assigned to the rhyme of the syllable, because only the rhyme determines weight; onsets typically do not contribute to syllable quantity:

```
(4) ... σ ...
      / \
     μ   μ
C   V   V    -->   heavy syllable with long vowel
C   V   C    -->   heavy syllable closed in a consonant
    ... σ ...
       |
       μ
  C   V      -->   light syllable
```

Bimoraic syllables typically attract stress and thus influence the stress pattern of a quantity-sensitive language.

Many languages have a requirement that their feet be no smaller in size than two moras (see below). Thus, in quantity-sensitive languages, in which certain syllables count as bimoraic, a quantity-sensitive foot (Ḣ) consisting of a single heavy syllable can b parsed. This foot is impossible in quantity-insensitive languages, in which all syllables count as light, for the purpose of stress assignment. As an example, take again the metrical structure of Seminole/Creek, this time considering a string containing a heavy syllable:

(5) iŋkosapitá 'one to implore'
(H)(LL)(LĹ)

Compare this example to (2d) above. Both examples are five syllables long, but because in this example the first syllable is heavy, it can form a foot of its own and parsing will resume right after it. Thus, the pitch accent falls on the final syllable, instead of the penultimate syllable, as in (2d).

Foot-size: Binary, Degenerate, Ternary, Unbounded

The maximal and minimal possible shape of feet is still a question open for debate. Feet typically have a binary structure, i.e., they consist of either two syllables or two moras. It might be necessary to admit the existence of smaller feet, though. So-called degenerate feet are feet consisting of a single light syllable. Monomoraic feet have been claimed to exist in languages such as Passamaquoddy (LeSourd, 1993):

(6) wìcohkémal 'he helps the other'
(*ò*σ)(*ó*σ)
wìcòhkekémo 'he helps out'
(*ò*)(*ò*σ)(*ó*σ)

Passamaquoddy parses quantity-insensitive, left-aligning trochaic feet. Stress on the first two syllables of odd-numbered strings, as in the second example, makes it necessary to analyze the structure as displaying two feet in initial position, the first one of which is degenerate. Even in languages in which normally feet are binary there are words in which degenerate feet seem to be parsed. This is the case for English *(é) (ssày)* or exceptional final stress in Italian (*cittá*, 'city').

It is less clear whether feet larger than binary are part of the inventory of possible feet across the world's languages. In fact, although morphological templates offer evidence for various types of binary feet (see later), no ternary or larger constituents have

been found so far in prosodic morphology (see Itô and Mester, 1992, for discussion of seemingly ternary templates in Japanese clippings). In the metrical literature, however, two types of larger feet, ternary amphibrachs and unbounded feet, have been proposed (see Kenstowicz, 1993, for evidence from tone shift for the existence of unbounded feet).

Take, for instance, languages with a ternary rhythm, such as Cayuvava (Key, 1961, 1967):

(7) ǰihiraríama 'I must do'
(σ̀σ)σ(σ́σ)<σ>
maràhahaéiki 'their blankets'
σ(σ̀σ)σ(σ́σ)<σ>
ikitàparerépeha 'the water is clean'
σσ(σ̀σ)σ(σ́σ)<σ>
čàadiròboβurúruče 'ninety-nine'
(σ̀σ)σ(σ̀σ)σ(σ́σ)<σ>

In Cayuvava, every third syllable counting from the right is stressed. This pattern can be analyzed as above as a structure where the final syllable is extrametrical (i.e., is excluded from the domain of stress assignment) and binary trochees are parsed from right to left with one syllable left unparsed between feet (Kager, 1993a; Hayes, 1995; Elenbaas and Kager, 1999). However, it also has been analyzed employing ternary feet. Thus, Halle and Vergnaud (1987) propose an analysis for Cayuvava where ternary amphibrachs (i.e., constituents whose head is not terminal) are parsed from right to left:

(8) maràhahaéiki 'their blankets'
(σσ̀σ)(σσ́σ)<σ>
čàadiròboβurúruče 'ninety-nine'
(σ̀σ)(σσ̀σ)(σσ́σ)<σ>

Feet unbounded in size have been proposed for languages without iterative stress. For instance, Koya (Tyler, 1969) is a language in which stress falls on every heavy syllable and on the initial syllable. Main stress is initial. Halle and Vergnaud (1987) analyze this pattern as a structure with unbounded feet where a foot starts at each heavy syllable and at the initial syllable:

(9) (ĹL)(ȊLLL)(ȊLL)

An analysis in these terms presupposes that feet are parsed exhaustively, i.e., all syllables are part of a foot. An analysis based on binary feet, by contrast, would maintain that some syllables of the word are left unparsed:

(10) (ĹL)(Ȋ)LLL(Ȋ)LL

The issue of exhaustive parsing, mentioned earlier, is thus closely connected to the question of binarity: theories maintaining that syllables are parsed exhaustively into feet must allow for feet that are larger than binary, whereas theories claiming that feet are necessarily binary have to dismiss exhaustive parsing.

Headedness: Iambs and Trochees

Feet can be divided into two groups with respect to the position of the head, i.e., the stressed element, inside the foot. Iambs are feet whose final syllable is stressed (the foot is right-headed) whereas trochees are feet whose initial syllable is stressed (the foot is left-headed). It has been observed that besides the position of the head there are other properties distinguishing iambic and trochaic systems. Iambic systems are typically quantity-sensitive, while we know both of quantity-insensitive and quantity-sensitive trochaic systems (Hayes, 1995). Moreover, as Hayes (1995) observes, iambic feet tend to enhance the quantity-contrast between the first and the second element of the foot, i.e., the unmarked iambic foot (LḾH) consists of an initial light and a following heavy syllable. The unmarked trochee, by contrast, consists of two elements that are equal in quantity. These observations have lead Hayes (1995) to propose the *Iambic/Trochaic Law* (see Kager, 1993a, for a proposal to derive the Iambic/Trochaic Law from independent principles of rhythmic organization such as constraints against stress lapses and stress clashes):

(11) Iambic / Trochaic Law (Hayes, 1995: 80)
a. Elements contrasting in intensity naturally form groupings with initial prominence.
b. Elements contrasting in duration naturally form groupings with final prominence.

Iambic and trochaic systems also differ with respect to the parameter of directionality. It has been claimed (Kager, 1993a; Hayes, 1995; Hyde, 2002; Alber, 2005) that although we find both right- and left-aligning trochaic systems, iambic systems are always of the left-aligning type.

Markedness Scale of Feet and Foot Inventories

Taking into account the Iambic / Trochaic law as well as the observation that heavy syllables attract stress and that feet are usually binary, Prince (1990) proposes to create a markedness scale for iambic and trochaic feet ("≻" means "is better than"):

(12) Iambic: (LḾ) ≻ (LĹ), (Ḿ) ≻ (Ĺ)
Trochaic: (ĹL), (Ḿ) ≻ (ḾL) ≻ (Ĺ)

The most unmarked iambic foot would thus be an (LḾ) foot, as this structure enhances the internal

quantity-contrast between the two syllables of the foot respecting at the same time the principle that heavy syllables should be stressed and the principle that feet should be binary. Iambic feet of the type (LÍ), (Ḿ) are binary as well and don't have any unstressed heavy syllables, but they don't respect the Iambic/Trochaic law. In fact, in (LÍ) and (Ḿ) feet the two elements of the foot – two syllables in the former, two moras in the latter – are of equal duration. Finally, the degenerate (Í) foot is the most marked foot, because it violates the principle of binarity. As for trochees, here the most unmarked feet are those in which both elements are equal in duration, whereas the uneven (ḾL) trochee is only second best (but see Mellander 2003 for (ḾL) forming processes).

This markedness scale coincides with the empirical findings of Hayes (1995), who observes that the foot-internal quantity-contrast in iambic systems is often enhanced by lengthening the second syllable of the foot, that trochaic systems avoid parsing an uneven (ḾL) trochee and that degenerate feet are strongly restricted in their occurrence. Hayes therefore proposes the following universal foot inventory that is asymmetric, reflecting the differences between trochaic and iambic systems:

(13) a. Syllabic Trochee (*σ́σ*)
b. Moraic Trochee (ÍL) or (Ḿ)
c. Iamb: (LḾ), (LÍ) if possible; otherwise form (Ḿ)

According to this universal foot inventory we will find both quantity-insensitive and quantity-sensitive trochaic systems (a and b), whereas iambic systems are usually quantity-sensitive (c). Moreover, the moraic trochee of quantity-sensitive systems is always even, (ḾL) trochees are not allowed in this inventory. Finally, iambs, differently from trochees, can be uneven, as the presence of the (LḾ) foot demonstrates (but see Kager, 1992, 1993b), who questions the existence of truly quantity-insensitive systems and Kager (1993a), who proposes to eliminate the (LḾ) iamb from the inventory of parsing feet. For an earlier proposal of foot typology, cf. Hayes (1980). For a foot inventory in terms of restrictions on heads and nonheads, see Hammond (1986). See Dresher and Lahiri (1991), who propose to add to Hayes's inventory the *resolved trochee* (Ḿ), (Í*σ*), i.e., a heavy syllable or a light syllable followed by a syllable regardless of weight, for which they find evidence in Old English and early Germanic in general).

Constraints on Feet

In Optimality Theory (Prince and Smolensky, 1993), the principles determining foot-structure are taken to be violable constraints. In fact, it has been observed that languages are not always consistent in their choice of a certain parameter determining foot shape. For instance, Prince and Smolensky (1993) observe that Southern Paiute (Sapir, 1930; Hayes, 1995), an otherwise iambic language, parses a final trochee in strings with an even number of syllables:

(14) pumpúŋkuŋwɨtàŋwa 'our (incl.) horses owned severally'
(*σσ́*)(*σσ̀*)(*σ̀σ*)

In terms of violable constraints, Southern Paiute can be analyzed as a language where a universal constraint requiring feet to be right-headed (RHTYPE = IAMBIC) dominates the constraint requiring feet to be left-headed (RHTYPE = TROCHAIC). Thus, generally, Southern Paiute will parse iambs, rather than trochees. In one special context, though – precisely, in word-final feet – the constraint RHTYPE = IAMBIC is itself violated. Prince and Smolensky (1993) propose that in this context we see the effect of the constraint NONFINALITY, a constraint militating against final stress and thus responsible for extrametricality effects. Because in this language NONFINALITY dominates RHTYPE = IAMBIC, the latter constraint is violated in order to satisfy the former. Table 1 illustrates this.

The competition between candidate a. and b. shows us that in strings with an odd number of syllables Southern Paiute behaves like a normal iambic language: since the constraint RHTYPE = IAMBIC is ranked above RHTYPE = TROCHAIC, the iambic parse in a. wins over the trochaic parse in b. In even-numbered strings, on the other hand, a final iamb would lead to a violation of the top-ranked constraint NONFINALITY (candidate b′.). Therefore, the final two syllables are parsed into a trochee, violating RHTYPE = IAMBIC, but satisfying NONFINALITY (candidate a′.).

The principles determining metrical structure thus are not simply on or off in a certain language but, rather, are the result of violable constraints interacting with each other (see also Alber, 1997, for quantity-sensitivity as the result of constraint

Table 1 Change of foot-type due to NONFINALITY

	NONFINALITY	*RHTYPE = I*	*RHTYPE = T*
☞ (a) (*σσ́*)(*σσ̀*)*σ*			**
(b) (*σ́σ*)(*σ̀σ*)*σ*		**!	
☞ (a′) (*σσ́*)(*σσ̀*)(*σ̀σ*)		*	**
(b′) (*σσ́*)(*σσ̀*)(*σσ̀*)	*!		***

interaction; Rosenthall and van der Hulst, 1999, for context-sensitive syllable weight; and Pater, 2000, for nonuniformity in English secondary stress assignment).

Two other constraints have been widely used to determine the shape of feet in optimality-theoretic analyses: the weight-to-stress principle (WSP) (Prince, 1990), responsible for generating quantity-sensitive systems and FT-BIN (Prince, 1980), favoring binary feet consisting of either two syllables or two moras:

(15) WSP: heavy syllables are prominent in foot structure and on the grid
Ft-Bin: Feet are binary at some level of analysis (μ, σ)
(Prince and Smolensky, 1993; see Kager, 1999, for a detailed overview on metrical constraints in general)

Evidence for the Foot as a Metrical Constituent

Evidence for the foot as a constituent comes from prosodic morphology, stress assignment, and foot-related phonological processes (for a detailed overview on evidence for the category foot, see Kenstowicz, 1993; for stress shift depending on metrical structure as evidence for the foot see Prince, 1975; Kenstowicz, 1994, and Kager, 1995).

The prosodic morphology hypothesis, as stated in McCarthy and Prince (1986/1996, 1990, 1993b, 1995), maintains that the templates found in the morphology of the world's languages are defined in terms of the units of prosody such as the mora, the syllable, and the foot. Work on reduplication, truncation, and word minimality restrictions has shown that we do find templatic morphemes that are bigger in size than a syllable but smaller than a prosodic word. Morphemes of this type should thus be evidence for the existence of the foot as a constituent.

One well-studied case in which templatic morphemes emerge is reduplication. For instance, in Manam, the reduplicative morpheme is a quantity-sensitive bimoraic foot. Exactly the two final moras, either in the form of two light syllables or one heavy syllable, are reduplicated:

(16) Manam reduplication (Lichtenberk, 1983; McCarthy and Prince, 1986/1996, 1993b, 1995):

salaga	salaga-laga	'long'
laʔo	laʔo-laʔo	'go'
malaboŋ	malabom-boŋ	'flying fox'
ʔulan	ʔulan-laŋ	'desire'

The analysis of the reduplicative morpheme as a bimoraic foot receives support from the stress-pattern of the language: main stress in Manam is assigned to a rightmost quantity-sensitive trochee, where syllables closed in a consonant count as heavy (long vowels do not occur):

(17)

siŋába	'bush'
L(ÍL)	
lúnta	'moss'
(Ḿ)L	
malabóŋ	'flying fox'
LL(ḿ)	

Note that without the concept of 'foot' as a prosodic constituent, the choice of two instead of three or four moras for the reduplicative morpheme would be completely arbitrary.

A bimoraic template is also found in the templates emerging in certain morphological processes of truncation. Consider Japanese, a pitch-accent language not making use of metrical feet as far as the stress pattern is concerned. Nevertheless, the foot plays an important role in its templatic morphology (Poser, 1984, 1990; Itô and Mester, 1992). Thus, in the formation of a particular type of hypocoristics, so-called 'rustic girl's names,' the first two moras of the name are used for the truncated form (Mester 1990; *o-* is a honorific prefix):

(18)

a.	Yuuko	–>	o-Yuu
			(H)
b.	Ranko	–>	o-Ran
			(H)
c.	Yukiko	–>	o-Yuki
			(LL)

Again, the choice of two moras instead of one, or three, is not accidental: the minimal quantity sensitive foot consists of exactly two moras, i.e., it consists of either one heavy or two light syllables. Thus, by using the category 'foot,' this type of hypocoristic formation can be described in a very simple way: the output of the morphological process must be a minimal foot, filled with the first two moras of the base name.

In many languages, there are requirements on the minimal length that a word must have. Typically, words must be at least bimoraic, i.e., consist of a heavy syllable (in quantity-sensitive languages) or of two syllables regardless of weight (in quantity-insensitive languages). Prince and Smolensky (1993) analyze such word-minimality effects as the result of a constraint LexWd ≈ PrWd (see also Prince, 1980), requiring every lexical word to correspond to a prosodic word, hence, to consist of at least one foot. One of the cases they present is Lardil (data originally from Hale, 1973), a language in which words must be at least two syllables long and in which this requirement is satisfied by blocking vowel apocope or by triggering augmentation:

(19)	Underlying stem	Nominative	Nonfut. Acc.	Gloss
	Apocope			
	a. yiliyili	yiliyil	yiliyili-n	'oyster sp.'
	b. mayařa	mayař	mayařa-n	'rainbow'
	No change			
	c. wiṭe	wiṭe	wiṭe-n	'inside'
	d. mẻla	mẻla	mẻla-n	'sea'
	Augmentation			
	e. yak	yak**a**	yak-in	'fish'
	f. maṛ	maṛ**ta**	maṛ-in	'hand'

In Lardil, final vowels are deleted in the nominative (examples a and b). Apocope is blocked, though, when deletion would generate a subminimal form, i.e., when the stem corresponds to the minimal word, which in Lardil is disyllabic (examples c and d). When the underlying stem is already subminimal (examples e and f), it is augmented in the nominative, in order to obtain a minimal disyllabic word (the nonfuture accusative suffix is *-in*; the vowel of the affix is deleted when it is attached to vowel-final stems. Augmentation takes two forms: the stem is augmented with a vowel, if the stem-final consonant is an illicit coda in Lardil, it is augmented with a consonant and a vowel, if the final consonant is possible in the coda; see Prince and Smolensky, 1993, for details). We see that Lardil employs various strategies to obtain the disyllabic template when words risk subminimality. Again, there is a reason for disyllabicity: a unit of two syllables forms a typical quantity-insensitive foot.

Yet another argument for the existence of the foot as a prosodic category comes from the typology of stress patterns. We know that certain types of stress patterns are more marked than others. As Hayes (1995: 47) notes, this fact can be best expressed by using a foot-based theory to classify them. Thus, it has been claimed that right-aligning iambic systems do not exist (see, e.g., Kager, 1993a; Hayes, 1995; Hyde, 2002; Alber, 2005). In foot-based theories, we can single out the right-aligning iamb as a marked structure, whereas without the iambic foot as a category we would have to describe this observation as "systems with stress on odd-numbered syllables counting from the right do not exist." Without the concept of foot, it would be a mystery why these systems should be absent from the typology whereas, for example, "systems with stress on odd-numbered syllables counting from the left" are attested (see also Kenstowicz, 1993, for quantity-sensitive iambic grouping vs. quantity-insensitive trochaic grouping as evidence for foot-structure).

Evidence for the category foot also comes from foot-related phonological processes. Iambic lengthening and trochaic shortening are both processes that target the foot as a domain and thus bear witness to its existence. It is one of the important findings of Hayes (1985, 1995) that iambic feet are typically uneven in length (see earlier), thus taking an (LH́) shape. In many languages, this shape is obtained by a process, iambic lengthening, which lengthens every even-numbered syllable in a string of light syllables. The typical trochee, by contrast, is even in length, i.e., it consists of either a single heavy syllable (H́) or two light syllables (ĹL). Hence, in trochaic languages we do find processes of shortening by which an HL sequence is transformed into an LL seLquence, which then can be parsed into an even (ĹL) trochee (Prince, 1990; Mester, 1994; Kager, 1993a). An example of this process is English Trisyllabic Shortening, a process by which the antepenultimate vowel of the word is shortened (Prince, 1990):

(20)			
	a.	ó:men	óminous
		(H́)<σ>	(ĹL)<σ>
	b.	sá:ne	sánity
		(H́)	(ĹL)<σ>

Assuming that the final syllable is extrametrical, English Trisyllabic Shortening thus is a process by which an HL sequence arising through suffixation (ó:men+ous) is transformed into an LL sequence, which then can be parsed into a canonical trochee. Prince points out that strikingly the element to be shortened here is the stressed syllable, contrary to the widespread believe that stressed syllables are always lengthened and unstressed syllables shortened. Trochaic shortening thus is not a process linked directly to stress but to the more abstract properties of foot structure.

Finally, there are phonological processes whose environment of application has been claimed to be the foot. An example for such a process is aspiration in English. Voiceless plosives are aspirated when foot-initial, but not when foot-medial: e.g., *a(tʰómic)* vs. (*átom)*. Glottal stop epenthesis in German also can be interpreted as being, at least in part, foot-related (Wiese, 1996). Thus, morpheme-internally glottal stops are inserted before vowel-initial syllables, when these syllables bear main stress (e.g., *chaʔótisch* 'chaotic' vs. *Cháos* 'chaos') and, for some speakers, also when they bear secondary stress (*Mícha*ʔ*èl*, 'proper name'). Note, that it could be argued that the concept of *stressed* syllable is sufficient for describing the context of application of these rules, we don't have to resort to the category foot. There are,

however, processes where referring to the stressed syllable is not enough. For instance, in Pacific Yupik, a language with iambic rhythm, foot-initial consonants undergo fortition (Leer, 1985a, 1985b). Thus in the following example, the first [k] is not realized as fortis, because it is foot-medial, whereas the foot-initial [t] undergoes fortition:

(21) akutamɔ́k '(kind of food) (abl.sg.)'
(LĹ) (L̲H́)

Note that differently from processes such as aspiration in English and glottal stop epenthesis in German fortition in Pacific Yupik cannot be interpreted as a simply being a correlate of the *stressed* syllable. Fortition in fact targets the unstressed – but foot-initial – syllable.

Foregrounding

What literature is, how it works, and why it exists at all are some of the fascinating questions that the theory of foregrounding tries to answer. The term 'foregrounding' refers to specific linguistic devices, i.e., deviation and parallelism, that are used in literary texts in a functional and condensed way. These devices enhance the meaning potential of the text, while also providing the reader with the possibility of aesthetic experience. According to the theory of foregrounding, literature – by employing unusual forms of language – breaks up the reader's routine behavior: commonplace views and perspectives are replaced by new and surprising insights and sensations. In this way, literature sustains or creates individual self-awareness of automatized actions and preconceptions. It thus contributes to general

creativity and development in societies. The theory of foregrounding is one of the few literary theories that has been tested empirically for its validity.

Foregrounding: The Term

The term 'foregrounding' may be used in a purely linguistic sense. In sentence structure, it then refers to new information, in contrast to elements in the sentence that form the background against which new elements are to be understood by the listener or reader. From this point of view, foregrounding bears resemblance to other (paired) linguistic concepts, such as theme/rheme, given/new, frame/insert, and subject/predicate. In the following discussions, the term will *not* be used in this narrow linguistic sense, but rather will be viewed as situated in the wider area of stylistics, text linguistics, and literary studies. There the term originates with Garvin (1964), who introduced it as a translation of the Czech *aktualisace,* a term common with the Prague Structuralists, especially Jan Mukařovský, who employs it in the sense of the English 'actualization.' This suggests a temporal category, i.e., to make something actual (rather than virtual). Garvin's translation has rendered this temporal metaphor into a spatial one, that of a foreground and a background. This allows the term to be related to issues in perception psychology, such as figure/ground constellations. It remains uncertain, however, whether this corresponds to what the Prague scholars had in mind.

In English, the term 'foregrounding' has come to mean several things at once. First of all, it is used to indicate the (psycholinguistic) processes by which – during the reading act – something may be given special prominence. Second, it may refer to specific devices (as produced by the author) located in the text itself. It is also employed to indicate the specific poetic effect on the reader. Furthermore, it may be used as an analytic category in order to evaluate literary texts, or to situate them historically, or to explain their importance and cultural significance. Finally, it is also employed in order to differentiate literature from other varieties of language use, such as everyday conversations or scientific reports. Thus the term covers a wide area of meaning. This may have its advantages, but may also be problematic: which of the above meanings is intended must often be deduced from the context in which the term is used.

Devices of Foregrounding

Outside literature, so the assumption goes, language tends to be automatized; its structures and meanings are used routinely. Within literature, however, this is opposed by devices that thwart the automatism with which language is read, processed, or understood. Generally, two such devices may be distinguished, those of deviation and those of parallelism. Deviation corresponds to the traditional idea of poetic license: the writer of literature is allowed, in contrast to the everyday speaker, to deviate from rules, maxims, or conventions. These may involve the language as well as literary traditions or expectations set up by the text. The result is some degree of surprise in the reader, and his/her attention is thereby drawn to the form of the text, rather than to its content. Cases of neologism, live metaphor, or ungrammatical sentences, as well as archaisms, paradox, and oxymoron (the traditional tropes), are clear examples of deviation.

Devices of parallelism are characterized by repetitive structures: (part of) a verbal configuration is repeated (or contrasted), thereby being promoted into the foreground of the reader's perception. Traditional handbooks of poetics and rhetoric have surveyed and described (under the category of 'figures of speech') a wide variety of such forms of parallelism, e.g., rhyme, assonance, alliteration, meter, semantic symmetry, and antistrophe.

Historical Background

It should be noted that, although formulated by the Prague Structuralists, the concept of foregrounding is not their own invention. In fact, foregrounding was a further historical development of ideas generated by the Russian Formalists, most notably those connected with the device of estrangement (Russian *priëm ostranenije*), as proposed by Viktor Shklovsky (*see* **Shklovsky, Viktor Borisovich (1893–1984)**). According to Shklovsky, the purpose of art is to make objects unfamiliar, so that a renewed perception of them creates a fresh awareness in the beholder, beyond the stale routines of automatized schemes. (Note, how also here, the perceptual metaphor plays an important role.) Thus, for Shklovsky (and his fellow Formalists), the devices used by writers are not merely there for ornamental reasons – they serve specific functions. Hence, the concept of foregrounding is also a theoretical one, which was later exported to the West by scholars such as Roman Jakobson, Felix Vodicka, and Rene Wellek. The theory was further refined in British stylistics, most notably by Geoffrey Leech (1969). (On the continuity between Formalism and Structuralism, see especially Erlich (1965) and Fokkema (1976); *see also* **Russian Formalism**).

Although in its present form the theory of foregrounding has been put forward most clearly in the

20th century, its roots can be traced back to Aristotle's *Poetics* (~335 B.C.E.). Time and again, Aristotle emphasized the fact that the literary text is made according to specific rules, and in this process, devices of deviation and parallelism play an important role. In *Poetics*, chapter 22, for instance, Aristotle stated that the diction of the literary work must be 'distinguished,' and that this effect is arrived at through the use of unfamiliar terms, metaphors, strange words, or lengthened forms. Through the influence of Aristotle's work from the Renaissance onward, this view of literature has gained a wide dissemination in Western culture. The theory of foregrounding can be seen as a more precise and more systematic elaboration of these ideas.

Descriptive Power of the Theory

The question should be asked whether foregrounding devices are universal. Few authors are explicit on this point, though in general the assumption seems to be that the answer should be positive. The presumed ubiquitous nature of foregrounding devices should not be taken in the sense that they all occur in literature all the time, but rather that various forms of parallelism and/or deviation do seem to form an integral part of the literatures of all known languages, cultures, and historical periods. If that is so, then the concept is a useful tool for analyzing and studying literature, both in the case of individual texts and in general.

This raises the issue of whether it is only a tool in the hands of the analyst, or whether processes of foregrounding also play a role in the mind of the reader. On the basis of empirical tests, it has been shown that the latter is the case. In a series of reading experiments, it proved to be possible, on the basis of the theory of foregrounding, to predict responses of readers to a number of texts. This was the case regardless of the readers' background or training. Research confirmed that a reader's attention is drawn by deviations, that these deviations cause the reader to process the text more slowly, that they cause an increase in affective responses to the text, and that they enhance aesthetic appreciation and change the reader's perception of the world outside the literary text (Van Peer, 1986; Miall and Kuiken, 1994; Hakemulder, 2004).

There are still several questions that remain to be answered. For example, when readers focus on the way a text is written rather than on its content, would this be a matter of convention or purely an effect that can be attributed to text properties? In other words, do readers process more carefully because they think literary texts are supposed to be read more carefully, or are they somehow forced by the text? Some research shows the influence of convention (Zwaan, 1993). Others studies, however, reveal that it is indeed foregrounding that causes such effects (Miall and Kuiken, 1994, 2001). Miall (1995) discussed how some research results in neuropsychology can be interpreted as support for the foregrounding theory. Hoorn (2001) conducted studies using electroencephalograms, revealing the cognitive-energetic surprise effect of literary metaphor processing. From his findings it can be concluded that semantic incongruency (foregrounding) causes a shock of surprise. Similar results have been found in experimental aesthetics (*see* **Literature: Empirical Studies**); complex and novel stimuli, including those in language, cause more arousal and hedonic pleasure than do common stimuli.

Not all of the research supports the hypotheses of foregrounding theory. Gibbs *et al.* (2002) examined emotional responses to literal statements, conventional metaphors, and novel metaphors. It was found that metaphors, compared to literal expressions, were rated as reflecting more intense speaker emotions, but contrary to what foregrounding theory would predict, no significant differences in responses to conventional and novel metaphors were found. However, on the whole, the results of reader response research reveal a clear tendency that favors foregrounding theory. (For text-oriented studies of foregrounding and how it may affect readers' aesthetic evaluation, as well as their interpretation of literary character and themes, see Simonton (1990), Culpeper (1996), Emmott (2002), and Van Peer (2002)).

Problems

The notion of foregrounding is not without problems. First of all, the relation between foregrounding and the evaluation of texts remains unclear. Does the presence of foregrounding devices increase a reader's sense of value of the text? There is only partial evidence for the existence of a relationship here. A more serious problem is the lack of a systematic inventory of devices and their relative importance. There is also terminological vagueness: are different terms, such as 'estrangement,' 'defamiliarization,' 'deautomatization,' 'foregrounding,' etc., synonyms, or do they correspond to slightly different psychological processes? In this respect, the similarities and differences with the more general (philosophical) notion of alienation through literature also should be clarified. A more precise description of the way in which the theory of foregrounding differs from other but similar theoretical constructs would also be welcome, e.g., Bertolt Brecht's theory of *Verfremdung* and similar notions in Surrealism, the Theater of the Absurd, and existential literature (the notion of aesthetic distance).

The Problem of Literariness

The presence of foregrounding devices in a text has often been used to determine the demarcation line between literary and nonliterary language. As has been observed by several linguists, however, foregrounding devices are also encountered in everyday language, e.g., in jokes, political slogans, nursery rhymes, and advertising texts. This has led most scholars to abandon the search for essentials of literariness, and to take a relativist stand, by concentrating on the conventional nature of what is called literature (*see* **Literature and the Language of Literature**). However, there may still be ways in which to solve the problem. To begin with, it is possible to distinguish between functional and nonfunctional cases of foregrounding. Perhaps only the former should be considered as literary. When someone accidentally produces an iambic pentameter in a scientific report, the formal structure does not in itself render it a case of foregrounding. Here Mukařovský's distinction between artifact and aesthetic object is useful. Second, we should not lose sight of the fact that some text genres (such as jokes, nursery rhymes, and advertisements) do display characteristics typical of literature, in form, function, and effect. The apparent problems of the concept of foregrounding in this respect are thus caused by the fact that the academic study of literature neglects a number of text genres (*see* **Genre and Genre Analysis; Text and Text Analysis**), such as oral texts, which are in no way categorically different from the texts traditionally studied in literature departments. If this is so, then the problem resides with the refusal of literary scholars to employ the term 'literature' in a descriptive, nonevaluative sense (*see* **Literature and the Language of Literature**). Finally, the problem may also be solved by pointing to the coherence and density of foregrounding, i.e., the degree to which the foregrounded elements can be integrated into the structure and interpretation of the work as a whole, or to the more systematic and consistent nature with which it is used in literary works (*see* **Cohesion and Coherence: Linguistic Approaches**).

A similar problem has arisen with respect to the device of parallelism. It has been demonstrated that patternings of the kind proposed by foregrounding theory may also be detected in scholarly articles, or in newspaper articles from *The Sunday Times*. In a sense, this is to be expected: because the repertoire of elements in a language (for instance, the number of phonemes) is finite, repetition is bound to occur. What has been overlooked in this matter, however, is the fact that the presence of patterns in nonliterary texts does not necessarily lead to new and/or interesting interpretations of those texts, nor do these patterns as a rule have a poetic effect on their readers. Presumably, parallelism in literary texts is distributed according to principles other than those of probability (as is the case in nonliterary texts). What is perhaps lacking most from the theory is a criterion for selecting those elements that are crucial to the literary functioning of the text.

Foregrounding and Literary History

The concept of foregrounding has been made use of most in textual analysis. It is a useful tool to describe particular characteristics of the text, or to explain its specific poetic effects on the reader. It may also fruitfully be employed to establish a link between a purely linguistic description and the functioning of literary texts in a culture at large. There is more to the concept of foregrounding than analyses of individual literary texts, though, and its importance should certainly not be reduced to this contribution.

Foregrounding has also been a useful concept in the study of visual arts and spectator responses (e.g., Krampen, 1996; Hakemulder, 2005). In this regard, it has played an important role in the Russian Formalists' approaches to film (Eagle, 1981). Their interest was partly inspired by the ideas and films of Sergei Eisenstein (e.g., *Battleship Potemkin*, 1925). Later, defamiliarization techniques were put to work by Bertolt Brecht, not only in his theater productions but also in films (*Kuhle Wampe*, 1931, and *Hangmen Also Die*, 1943). In general, in the visual arts, foregrounding refers to drawing spectators' attention to some element in a film by means of unusual filmic devices. Wollen (1982) refers to foregrounding to define counter-cinema (opposing mainstream cinema); for him it describes the spectators' focus on processes of construction of meaning. Examples would be fixed positioning of the camera, and the deformation of familiar objects through filters, mirrors, and extreme close-ups. Of immense impact on film studies is the work by Bordwell (1985), who was also influenced by the ideas of Russian Formalists, and for whom deautomatization is a central concept in the study of film. In his terminology, foregrounding is a deviation from intrinsic norms.

Foregrounding theory can help in conceptualizing literary history. By inspecting the way in which foregrounding operates in the literary system at large, its importance for the historical study of literature may transpire. It is conceivable that foregrounding devices may, because of their very use, lose their defamiliarizing potential, and thus they stand in need of constant replacement. In this way, history can be

viewed as a continuous wavelike substitution and renewal of the devices and processes by which foregrounding operates. The individual work of literature exists in an unavoidable tension between its conformity to tradition and the pressure it is under to add some innovative aspect to this tradition. Literary history, then, is the never-ending relief of new ways in which foregrounding is brought about and experienced (see Martindale, 1990).

Abstract:

What literature is, how it works, and why it exists at all are some of the fascinating questions that the theory of foregrounding tries to answer. The term 'foregrounding' refers to specific linguistic devices, i.e., deviation and parallelism, that are used in literary texts in a functional and condensed way. These devices enhance the meaning potential of the text, while also providing the reader with the possibility of aesthetic experience. According to the theory of foregrounding, literature – by employing unusual forms of language – breaks up the reader's routine behavior: commonplace views and perspectives are replaced by new and surprising insights and sensations. In this way, literature sustains or creates individual self-awareness of automatized actions and preconceptions. It thus contributes to general creativity and development in societies. The theory of foregrounding is one of the few literary theories that has been tested empirically for its validity.

Biography:

Jèmeljan Hakemulder's background is in literary theory and comparative literature. He conducted his Ph.D.-research (1998) at the department of Literary Studies at Utrecht University and the Department of Psychology at the University of Illinois (Urbana-Champaign). He specialized in the psychology of literature, focusing on the effects of reading literary texts on attitudes. On this subject he published several books and articles, among which *The moral laboratory. Experiments examining the effects of reading literature on social perception and moral self-concept* (Amsterdam: Benjamins, 2000), and in 2004 "Foregrounding and its effects on readers' perception" (*Discourse Processes, 38,* 193–218). From 1998 to 2001 he conducted his (post-doc) research at the Free University of Amsterdam, looking at aspects of literary communication that may be responsible for the effects of reading on intergroup attitudes. Since 2001 he is an assistant professor at the Institute for Media and Representation (Utrecht University), and conducts studies concerning the reception of film.

Biography:

Willie Van Peer studied linguistics, literature, and philology. He received his Ph.D. in 1980 from the Department of Linguistics of Lancaster University (UK). After teaching jobs in Belgium and Algeria, he worked in text linguistics at the University of Tilburg and in theory of literature at Utrecht University, both in the Netherlands. He was appointed to the professorship of Intercultural Hermeneutics in the Department of Languages and Communication at the University of Munich in 1997. His main areas of research are the theory of literature, stylistics, intercultural studies, and the empirical study of literature. He is the author of *Stylistics and Psychology: Investigations of Foregrounding* (London: Croom Helm, 1986) and editor of *The Taming of the Text. Explorations in Language, Literature, and Culture* (London/NewYork: Routledge, 1988). Together with Seymour Chatman he edited *New Perspectives on Narrative Perspective* (Albany, NY: SUNY Press, 2001); with Max Louwerse he edited the interdisciplinary volume *Thematics. Interdisciplinary Studies* (Amsterdam/Philadelphia: John Benjamins, 2002).

Defining Foreign Languages

As used here, the term 'foreign language teaching' refers to two phenomena: (a) the provision in one country of instruction in a language whose home base is another country, and (b) instruction in a transnational language such as English or Arabic whose identification with a particular country is minimal. Policies with respect to both of these phenomena will be referred to as foreign language policies. In most countries, the second type of foreign language is becoming more important than the first in foreign language teaching policy.

It is also important to note that in many countries the division between domestic and foreign languages is imprecise. In Canada, French is a regional language, serving as the official language of Quebec, and it is the first non-mother-tongue language taught to children in the non-Francophone portions of Canada, and it is also taught as a foreign language. Tamil is both a domestic and a foreign language in Sri Lanka. Turkish and Arabic are both foreign and immigrant languages in many of the cities of Europe. Spanish was at first an immigrant language in the United States. It has become a strong regional language in California, Florida, and the American southwest, and it is the foreign language with the largest enrollment in schools and colleges throughout the United States. Modern Standard Arabic is taught in countries in the Maghreb and the Middle East, where it is often used in official and educational venues, but it is somewhat different from the spoken vernaculars in those countries.

Foreign Language Policy Decisions

With respect to the teaching of foreign languages, there are a number of interconnected policy decisions that administrators and educators must make. First, they must decide the relative emphasis to give to foreign languages in both educational and public affairs. In addition to this general decision, there are a series of more specific architectural decisions about the organization of foreign language teaching in the formal education system that have to be made: (a) when to start foreign language instruction; (b) what proportion and what kinds of students will receive foreign language teaching as a mandatory or as an optional subject; (c) in what grades and for how many hours or years should foreign languages be taught; (d) should the foreign languages be taught as subjects to be studied or as media of instruction in teaching other subjects; (e) how many and which languages should be taught; (f) how should standards of achievement be set and assessed, and (g) how to recruit and train teachers. With a few exceptions, in most countries the precise form of foreign language pedagogy to be used is not the subject of official policy, leaving the choice to individual teachers and textbook publishers.

Categories of Countries by Linguistic Context

While most scholarly attention to foreign language policy has concentrated on Europe, it is instructive to examine it more broadly throughout the world. In doing so, it is useful to divide countries into a number of categories according to differences in the linguistic contexts in which they teach foreign languages. Each of the linguistic contexts makes a difference in both the emphasis given to foreign language education and how the system is structured. The classification of countries used here is (1) mosaic countries with a large number of important domestic languages; (2) monolingual countries where languages other than English are the primary mother tongue; (3) English-mother-tongue countries, (4) Continental Europe. The rank order of these categories roughly parallels differences in the relative importance of foreign language teaching, ranging from little to highly important.

Mosaic Countries with Numerous Important Domestic Languages

The majority of countries in the world have five or more important indigenous languages. In many such countries, the overwhelming language policy issues are concerned with the development and relative standing of multiple national languages, and the languages of major important regional minorities, autochthonous peoples, and immigrant groups. Foreign language instruction tends to be given limited importance. This situation is characteristic of many of the countries of Africa where the official status of the many indigenous languages is under negotiation,

and where corpus language policy issues such as the determination of standard versions of indigenous languages, the development of scripts, the promotion of literacy, and the management of the transition from vernaculars used in the home to standardized school languages are still major tasks for language policy makers. Where foreign language instruction is developed in mosaic countries, the language studied tends to be English as a world language, and to a lesser extent French, in former French colonies. In many of the latter countries, the proportion of students enrolled in the study of English as opposed to French is rising. In Cambodia, for instance, when students are given a choice, they choose English over French by a two-to-one margin. In Vietnam, another former French colony, about 90% of the schools teach English as the first foreign language.

Where colonial or foreign languages are taught in mosaic countries, the teaching tends to be in private schools, or, when in public schools, at the secondary and tertiary levels, often on an optional basis. Knowledge of the colonial language serves as a screening device for upward mobility and entrance into the cosmopolitan environment. Only rarely is more than one foreign language offered or taken in mosaic societies.

Non-European Linguistically Homogeneous Countries

In countries outside of Europe where a single domestic language predominates, foreign language instruction tends to concentrate almost exclusively on English. In Japan, for instance, the teaching of English has been a focus of language policy since the Meiji restoration, although only recently for the general populace. Although the study of English is not a compulsory subject, 90% of Japanese students receive English instruction. Other foreign languages are given much less emphasis. When taught, non-English foreign languages tend to be in private schools, in universities that specialize in the teaching of foreign languages, and in schools that prepare business people for foreign assignments.

The teaching of English presents special problems for countries such as Japan, whose home languages belong to unrelated language families. For one thing, students take considerably longer to master the language. Second, it is difficult to train teachers so that they can approximate native speakers and can employ teaching strategies different from those they are accustomed to in learning or teaching their own language. The Japanese solution to these problems is to import British and American students to serve on a temporary basis as native speaker assistants in Japan and to send Japanese teachers into classrooms in the United States in which Japanese is taught to perform similar functions and to observe American language teaching styles. Other countries use study abroad for raising the command of English among their teachers, and the development of country-specific varieties of English enable countries to train their teachers at home.

A similar emphasis on the teaching of English is found in most Southeast Asian countries—Brunei, Burma, Hong Kong, Indonesia, Laos, Malaysia, Philippines, Singapore, and Thailand—and in the countries of Central and South America. China, while a mosaic country with extensive internal linguistic variety, with respect to the teaching of foreign languages it acts like a monolingual society, promoting the overarching *lingua franca* Putonghua, and it teaches English as the primary foreign language. English is taught selectively in some secondary schools, and China is experimenting with requiring it at the college level.

Israel has a large (18%) Arabic-speaking minority which by and large resides in a separate sector of the country. In the Jewish sector, 60% of the population was born outside of the country and speaks a wide variety of languages. The official government statement on foreign language teaching, *1996 Policy for Language Education in Israel*, makes provision for language maintenance of immigrant languages. However, in language policy, it tends to act like a non-English speaking monolingual or bilingual country. The official language of Israel is Modern Hebrew, but in the Palestinian portion of Israel, Modern Standard Arabic is taught. In the two linguistic sectors, the teaching of each other's language is required. Foreign language instruction is by and large confined to English, which all students are required to study at the elementary and secondary levels.

English-Mother-Tongue Countries

In all of these countries, the presence of English, the world language—one that is predominant in international discourse, in science, business, and in a large sector of the popular entertainment culture—lowers the motivation for governments and educational institutions to teach other languages and, most important, for students to study them. The more general humanistic motivations for studying a foreign language—personal enrichment and multicultural understanding—are less persuasive to both students and educational administrators.

Furthermore, in each of the English-mother-tongue countries, policy toward domestic languages demands a substantial amount of attention. In New Zealand,

the primary issue is the maintenance of Maori. In the UK, it is the support of regional minority languages: Welsh and Gaelic. In Ireland it is the rejuvenation of Irish. In Australia it is the maintenance of the aboriginal languages, and support for immigrant languages, there called 'community languages.' In the UK, it is problems with the languages of the South Asian immigrant communities. In the US, it is the provision of early education in the home language for immigrant children legally designated as having Limited English Proficiency (LEP), some 3 million students, or about 6.7% of all students. Three-quarters of LEP students are Hispanic.

The countries where English is the mother tongue may in turn be divided into two categories: (a) those located in continents far from Europe such as Canada, Australia, and the US; and (b) the UK and Ireland in which the foreign language teaching system is a more limited version of mainland Europe.

Category (a) English-Mother-Tongue Countries Distant from Europe The major countries in category (a)—Canada, Australia, and the United States—have extensive foreign language teaching systems, but in scale and reach they are considerably more limited than in those in Continental Europe. They tend to start later, reach a smaller per cent of educational institutions, are less mandatory, and have sharp drops in enrollment and major pedagogical gaps across educational levels.

Foreign language policy making in each of these countries is largely decentralized, the responsibility of provincial, state, or local governments, or, in the United States, of individual school districts, schools, and teachers. Accordingly, the language educational systems vary significantly from one section of the country to another, with some sections relatively strong in foreign language teaching and other sections weak. Australia has had a number of attempts at centralized policy making for foreign language teaching systems (Lo Bianco, 1987), and for several decades the study of foreign languages has been actively promoted both by government and by university-based centers established for this purpose. However, support by the Commonwealth government has waxed and waned over the years. The United States has no mechanism for national foreign language planning, nor has there been any sustained national advocacy for the expansion of the foreign language teaching system. Moreover, all policy, where there is one, is made at the level of the state, the school district, and the individual teacher.

In one respect, category (a) English-mother-tongue countries distant from Europe have more fully developed foreign language educational systems than the UK and Europe. Because they do not need to teach English as a foreign language, and because the expectation is somewhat less that their citizens will come to actively use their foreign language competencies as adults, particularly with respect to European languages, the choice of which languages to teach is somewhat freer. Accordingly, each country has dedicated a portion of its system to expanding the geographic coverage of the languages taught. In the western part of Canada, the substantial immigration from Asia has increased the number of students who elect to study Asian languages. Australia has provided substantial Commonwealth government support to an initiative called National Asian Languages and Studies in Australian Schools (NALSAS). Its goal was to expand the coverage of Asian languages. As a result, in 2000 some 23.4% of Australian students, about 750 000 of all students, were studying an Asian language.

In the United States, which languages are taught is heavily influenced by the preferences of students, and they have drifted away from traditional European languages. Before World War I, most students who studied a foreign language in school were enrolled in Latin and Greek. In the early decades of the twentieth century, language choice followed the British and European pattern of emphasizing German and French. In recent years, enrollments in the United States have shifted overwhelmingly to Spanish, not as a European language but as a language of the Americas. In addition, U.S. governmental policy has fostered the growth of instruction in a great many of the non-Western languages of East Asia, Eastern Europe, and the Middle East. They were introduced first in the universities but are now spreading into colleges and secondary schools. Even primary schools have seen an increase in the study of non-Western languages. While they represent only 2% of enrollments in secondary schools, led by Chinese and Japanese, their enrollments have been increasing. At the collegiate and university level, 21% of the students enrolled in foreign language classes are studying a non-Western European language. It takes longer for English speakers to master these languages. According to the Defense Language Institute in the United States, which teaches many languages, it takes about five times longer for an English speaker to learn Japanese or Chinese than to learn French or German. As a consequence, a number of architectural challenges arise for foreign language teaching systems: a shortage of qualified teachers; low enrollment classes, particularly at the advanced level; and special problems of using immigrant native speakers as

instructors who are untrained in foreign language pedagogy and have a limited knowledge of the language of the students they are teaching.

The individual countries in category (a) differ considerably in the architecture of their foreign language teaching systems. Canada is a prime example of a linguistically binary country (Lambert, 1999), that is, a country in which two sections of the country have different mother-tongues—in this case English and French. The rationale for Canada's bilingual education program is primarily domestic, the promotion of a single national identity in a culturally divided country. It is not the promotion of foreign language skills. If the teaching of French in the Anglophone sections and the teaching of English in Quebec were considered foreign language instruction, Canada's foreign language education system would be among the most extensive in the world. Indeed, its innovations in second-language teaching have introduced a variety of new pedagogical practices, particularly in the development of immersion language instruction, which have influenced foreign language instruction throughout the world. In the full-immersion system, children start to study the second language in early primary school years, and throughout their schooling a variety of subject matter courses is taught in the second language. Second-language instruction can require up to 5000 hours of instruction time in the primary and secondary school years, although most students receive a lesser amount of language education.

In Australia, most states and territories require students to take at least 3 years of a foreign language. Language education generally starts in primary school, but in the early years it is primarily aimed at cultural awareness rather than skill acquisition. In many states, language study is mandatory from mid-primary school through grade 8 when compulsory language instruction stops. This results in a huge drop in enrollments in school years 9 and 10, when fewer than 50% of students study languages other than English. By year 12, the per cent has dropped even further to only 13.2%. One survey noted: "The general level of language study in Australia has fallen dramatically in the past twenty-five years. In the 1960s, about 40% of final year school students studied a language other than English. Today fewer than 1% of all higher education students complete a language unit at any stage in their course" (Erebus Consulting Partners, 2002: Chap. 2, p. 11).

In the US, only about one-third (31%) of elementary schools offers foreign language instruction, but only about 15% of all students receive it. Moreover, in elementary school at least half of the courses tend to be pointed toward general language familiarization rather than the attainment of proficiency. As in Australia, most of them provide less than two hours per week of language instruction. While 86% of U.S. secondary schools provide foreign language instruction, usually for five hours per week, enrollment is generally optional, and 40% of secondary school students receive no foreign language instruction at all. Moreover, the duration of language study tends to be limited—80% of enrollees receive two years or less of language study. Only about 50% of the students enrolled in any one year of language study continue to the next level. In the year 2000, only 13.2% of all students at grade level 12 were enrolled in foreign language courses (Lambert, 2000), and only about half of secondary school students receive any foreign language instruction at all. A substantial portion of students who study a foreign language begin that study at the college level. Half of these post-secondary institutions require that by the time their students graduate from college they have had some foreign language study at some point in their education, sometimes just a year. However, only 10% of all college students study any foreign language while they are in college.

Although the United States has no mechanism or tradition of centralized language planning, there has been one major governmental initiative born in its diplomatic and military training programs that has had a major effect on foreign language teaching policy throughout the country. Those government schools and training programs developed a system of oral interviews and a laddered scale of descriptors to measure the level of language proficiency. This technology was adopted by one of the major foreign language teachers' organizations, the American Council on the Teaching of Foreign Languages (ACTFL), which diffused it widely throughout the field. The ACTFL scale together with the development of a related set of language-specific standards, effectively promoted the shift from the grammar-translation pedagogical style to the more interactive, oral, less grammar-oriented pedagogical style.

Category (b) English-Mother-Tongue Countries in Europe In those English-speaking countries neighboring continental Europe—the UK and Ireland—the scale of their foreign language teaching systems falls midway between the more fully developed systems in Europe and the other, distant from Europe, English-mother-tongue countries. Like the other English-speaking countries, the UK accommodates several regionally distinct languages—Welsh and Gaelic—but the domain of those languages remains almost

entirely within the UK, in Wales and Scotland, on home territory.

With respect to the study of foreign languages, the UK remains behind its European partners in total modern foreign language education. In continental Europe, pupils start earlier and continue longer.

In the UK in general, the National Curriculum for Modern Foreign Languages requires by statute the study of a foreign language in secondary schools where the average amount of time is 140 minutes per week or about 10% of classroom time. Achievement levels also are nationally specified. The intention is to have all students from ages 11 to 16 study a foreign language for about 120 minutes per week. Students can opt to study a second language in secondary school, but only 5% of the students do so, down from 10% five years earlier. The government has made the study of any foreign language optional for all 14- to 19-year-olds and limited statutory requirements to 3 years, resulting in a 50% drop in instruction in state schools. This would be offset by the provision of an entitlement program making foreign language instruction available at the primary level. The study of a foreign language in upper secondary school is optional, and only about 10% of the students study one. It is predicted that this will result in the wholesale dropping of language study by vocationally oriented students.

Throughout the school system, instruction in modern foreign language is heavily concentrated on the Western European languages: 62% in French and 25% in German, although the number of students sitting for A-level exams in Urdu, Russian, and Japanese has increased. As in the United States, England has a substantial amount of foreign language education in higher education. It may be taught in a language or discipline department or in a school of foreign languages that serves both majors and students training to be specialists in other disciplines. Languages may be taught *ab initio* for beginning students or advanced for those who have taken A level exams in a language prior to admission. At the university level, 34% of the courses given are in French and 32% in German. The rest of the courses are primarily in Italian or Spanish.

England has played a central role in the development of pan-European language policy in the Council of Europe and in such collective foreign language advocacy efforts as Europe's Year of Language. It has had major continuing foreign language advocacy centers such as The Centre for Information on Language Teaching and Research (CILT) and the Nuffield Foundation.

Ireland's foreign language educational system resembles that of the UK but on a somewhat smaller scale. It does not make the study of foreign languages a compulsory subject. Rather the emphasis is on the teaching of Irish, the historic language of the country. However, in practice most students do study a foreign language. For instance, students in the 12- to 14-year-old age group spend about 140 minutes per week in the study of foreign languages. As in the UK, the languages most frequently studied are French and German.

Continental Europe

In many respects, the home of foreign language instruction lies in Europe. In terms of the policy decisions that must be made, most of these countries start foreign language instruction earlier, promote it more aggressively, make it more compulsory, continue it longer, require or recommend that each student study a larger number of languages, assess it more deliberately and consistently, are more likely to use it as a medium of instruction, are more likely to establish a centralized assessment system, and are more systematic in developing explicit national policies than the countries in the other three linguistic categories of nations.

The enhanced scale and strength of European foreign language teaching systems rest in part on the fact that a majority of the population—53% according to a Eurobarometer survey of residents more than 15 years of age (European Commission, 2003)—reports the capacity to carry on a conversation in a foreign language, and the proportion is even higher for younger age groups. Moreover, 93% of those surveyed believe it is important that their children learn other European languages. There is some variation among European countries in the extent of adult multilingualism. The Luxembourgers, Netherlanders, and Danes do best, while Russians, Spaniards, and Poles report less competency. The French come somewhere in the middle. The level of adult support for multilingualism is both cause and effect in determining the scale of foreign language teaching systems.

There is a considerable difference among countries in the architecture of foreign language teaching. A number of comparative inventories are available that compare different systems (Bergentoft, 1994; Dickson and Cumming, 1996; Eurydice, 2000). John Trim describes some of the major determinants of the scale of development of foreign language teaching within European countries. He reports that "a country is more likely to value L2 proficiency if (1) it is internally multilingual (established territorial minorities); (2) it is a small country, but not

geographically or politically isolated; (3) its neighbors speak a different language; (4) its own language is not widely spoken and not used as a vehicle for international communication; (5) its export/import trade is a higher percentage of GDP; and (6) its travel trade is a higher proportion of foreign trade and GDP." (Trim, 1994: 12).

In addition to differences in overall scale, individual countries within Europe make different choices in the various features of their language policy. Traditionally, the study of a foreign language was a requirement for the academically oriented. Now almost all European countries by law require the study of at least one foreign language for all students. In many countries, the study of two foreign languages is required—for instance, in Belgium, Denmark, Finland, Greece, The Netherlands, and Sweden—and in the others the study of a second foreign language, while provided, is voluntary, with schools and students given varying degrees of choice. There is more variation in upper secondary education, where some academic specialties such as classics, humanities, economics, and the social sciences emphasize foreign language learning, and other academic specialties do not. In many of these countries, there are schools specializing in foreign languages.

One of the indicators of the degree of a country's commitment to foreign language study is the age at which the first foreign language appears on the compulsory curriculum. In most European countries students must start learning a foreign language between the ages of 8 and 12. In Austria, Italy, Luxembourg, and Norway, they start at age 6 or 7. Most students continue language study for about 10 years, receiving from 135 to 180 minutes per week in language classes. Most countries only teach foreign languages as subjects, using them as media of instruction in limited subject matter areas such as science or special, vocationally oriented courses such as travel and trade. Luxembourg, however, maintains a full-immersion system with all subject matter courses taught in French or German throughout the educational system, as well as Letzeburgisch, the local language. Their students tend to go to France or Germany for advanced education.

One of the most important language policy issues that tend to be determined at the national level is which foreign languages to teach and in what order. While the international goal is the creation of a pluralistic Europe in which all citizens learn the languages of one or a number of other countries of the region, in almost every country in Western Europe the first foreign language taught and taken by most students is English. In the binary and triad countries such as Belgium and Switzerland, the predominant languages taught—French, German, or Italian—are those of both an internal linguistic region and of a neighboring country. In the countries of Eastern Europe that were formerly under Russian hegemony, German is often substituted for the formerly compulsory Russian, but the teaching of English is spreading.

Almost all European countries have explicit, comprehensive foreign language plans. Sometimes they result from private surveys exploring existing strengths, needs, and weakness, such as the The Netherlands's *Horizon Taal* (van Els, 1990) or the Nuffield Foundation surveys (Moys, 1998). More often, these plans comprise the organization and specific goals of foreign language study (e.g., Sweden's National Agency for Education, 2001). One of the most remarkable aspects of European language policy is the influential role of international organizations—in particular, the Council of Europe and the European Union—in advancing foreign language teaching policy across Europe.

Since the adoption of the European Cultural Convention in 1954, the Council of Europe has been engaged in creating a transnational consensus on foreign language teaching policy. Its varied activities have had an immense impact on member countries' own policies. The Council assisted in countries' assessments of their language needs. It was central to the transformation of language pedagogy from a grammar-translation format to one emphasizing communicative language competence. It developed manuals setting learning objectives and goals for several levels of foreign language proficiency. The first manual, published as *Threshold Level 1990* (van Ek and Trim, 1998) changed the focus of language teaching from what the learner needs to know to what he or she must be able to do to function adequately in a foreign language. The first and most general model, the Threshold Level, has been formally adopted throughout Europe to cover 20 languages. Using a similar approach, a Waystage model was also developed for a more elementary level of competence, and later, a model for more advanced learners called Vantage Level. The Council (Council of Europe, 2001) issued a more comprehensive Common European Framework of Reference for Languages: Learning, Teaching, Assessment. It covers more generally a wide variety of policy issues in language learning. It also establishes a hierarchy of levels of language proficiency that can be used across languages and countries in Europe. This skill hierarchy differentiates

proficient, independent, and basic language users, and provides specific skill level descriptors for listening, speaking, and writing. This general scaling of language competencies as expressed in the Common European Framework is intended to be applicable across languages and countries (Language Policy Division, 2003). A number of countries, e.g., The Netherlands and England, have already begun to calibrate their own systems of ranking language skill with those of the Common Framework, and more countries are working toward that end. Moreover, these internationally agreed upon scales of competency are also intended to be used by individual learners in making up a language portfolio to provide evidence of their language skills for use in education, transnational employment, or international travel.

In the other major European international organization, the European Union (EU), during the early years, in matters relating to foreign language policy attention was concentrated primarily on matters of economic or vocational relevance. The European Commission has adopted a much wider perspective on the promotion of foreign language learning throughout Europe (European Commision, 1997). Specific EU funding programs have been especially productive in enhancing the foreign language education system. The LINGUA program within SOCRATES supported training opportunities for language teachers to study abroad. The LEONARDO DA VINCI program supported the development of language skills for international business. A new program, COMENIUS, is primarily concerned with language education in schools.

Future Developments

It is difficult to predict the future of foreign language teaching policy. How long the seemingly universal trend of teaching English as the first foreign language will continue is unclear. There are some who hope its role will diminish (Phillipson, 2003) and others who predict its hybridization and possible loss of supremacy (Graddol, 1997, 2004). Were English to cease being the first foreign language to be taught around the world, it is difficult to predict what would succeed it. The perennial drive to spread the use of Esperanto as a common world language has had only modest success (Corsetti, 2003). And whether Europe will complement its inward-looking policy and adopt a broader range of foreign languages to teach is problematic. However, the teaching and learning of foreign languages will remain high on the world's agenda.

Formal Models and Language Acquisition

N Chater, University of Warwick, Coventry, UK

© 2006 Elsevier Ltd. All rights reserved.

The project of understanding how children acquire language faces enormous empirical challenges in characterizing the development of children's linguistic knowledge, understanding how that knowledge arises (given innate constraints and linguistic and non-linguistic input to the child) and specifying the neural, cognitive, and social processes in which language acquisition is rooted. But an equally substantial challenge concerns the theoretical problem of language acquisition. How, in principle, is it possible to derive the spectacular richness and complexity of adult linguistic performance from the apparently unsystematic and impoverished input available to the child?

Formal models of language acquisition attempt to address this question: to explain how language acquisition is possible at all. The strategy of formal models is abstraction. Rather than attempt to incorporate the detailed knowledge that has been obtained through empirical research, formal models typically focus on a highly schematic and idealized picture. This high level of abstraction in inevitable, if a mathematical analysis of the acquisition problem is to be viable. Just as in any area of natural or social science, extreme simplification is a precondition for mathematical analysis. It is also, arguably, desirable in any case, because simplifications allow a clarification of core theoretical and empirical issues, which might otherwise be buried in endless details. Nonetheless, idealization has its perils. We shall see below that the particular idealization adopted of different aspects of the learning problem can often be of great theoretical significance.

The rather abstract character of formal models of language acquisition has a very different flavor from the much more concrete and descriptive character of most psychological and linguistic research into how children learn language. Formal models frequently abstract away from details that much of the rest of the field of language acquisition research is concerned to characterize.

Ultimately, though, empirical and formal approaches to language acquisition are unavoidably intertwined. Attempts to develop broad theoretical arguments concerning how children learn language, which are crucial to organize and understand the wealth of empirical data, inevitably involve radical abstraction and idealization. For example, arguments for innateness based on the poverty of the stimulus (and counter-arguments against this position) are pitched at just the high level of abstraction that demands, and has received, formal attention. More broadly, just as in other areas of science, it is reasonable to demand that informal theoretical claims can be made formally rigorous, at least in certain idealized settings. Yet just as the empirical study of language acquisition needs formal models, so equally do formal models rely on the results of empirical research to set out the key phenomena that a theory of language acquisition must capture.

In the rest of this article, we introduce the problem of language acquisition in general terms, as a problem of inductive learning, and outline certain general puzzles concerning how learning of this type is possible. We then consider a range of specific formal analyses of aspects of the learning problem and we shall see that different idealizations appear to support very different qualitative conclusions about the nature of language acquisition. We shall, moreover, attempt to connect the discussion of formal modeling work with empirical constraints, qualitative theoretical analysis and computational modeling, emphasizing that formal models of language acquisition should be integrated with the wider scientific problem of understanding how children acquire language.

Language Acquisition as Induction

It has become standard to view the problem facing the child in the following terms. Language is governed by a highly complex set of regularities; the child is exposed to a finite set of examples of linguistic stimuli

Formal Models and Language Acquisition

N Chater, University of Warwick, Coventry, UK

© 2006 Elsevier Ltd. All rights reserved.

The project of understanding how children acquire language faces enormous empirical challenges in characterizing the development of children's linguistic knowledge, understanding how that knowledge arises (given innate constraints and linguistic and non-linguistic input to the child) and specifying the neural, cognitive, and social processes in which language acquisition is rooted. But an equally substantial challenge concerns the theoretical problem of language acquisition. How, in principle, is it possible to derive the spectacular richness and complexity of adult linguistic performance from the apparently unsystematic and impoverished input available to the child?

Formal models of language acquisition attempt to address this question: to explain how language acquisition is possible at all. The strategy of formal models is abstraction. Rather than attempt to incorporate the detailed knowledge that has been obtained through empirical research, formal models typically focus on a highly schematic and idealized picture. This high level of abstraction in inevitable, if a mathematical analysis of the acquisition problem is to be viable. Just as in any area of natural or social science, extreme simplification is a precondition for mathematical analysis. It is also, arguably, desirable in any case, because simplifications allow a clarification of core theoretical and empirical issues, which might otherwise be buried in endless details. Nonetheless, idealization has its perils. We shall see below that the particular idealization adopted of different aspects of the learning problem can often be of great theoretical significance.

The rather abstract character of formal models of language acquisition has a very different flavor from the much more concrete and descriptive character of most psychological and linguistic research into how children learn language. Formal models frequently abstract away from details that much of the rest of the field of language acquisition research is concerned to characterize.

Ultimately, though, empirical and formal approaches to language acquisition are unavoidably intertwined. Attempts to develop broad theoretical arguments concerning how children learn language, which are crucial to organize and understand the wealth of empirical data, inevitably involve radical abstraction and idealization. For example, arguments for innateness based on the poverty of the stimulus (and counter-arguments against this position) are pitched at just the high level of abstraction that demands, and has received, formal attention. More broadly, just as in other areas of science, it is reasonable to demand that informal theoretical claims can be made formally rigorous, at least in certain idealized settings. Yet just as the empirical study of language acquisition needs formal models, so equally do formal models rely on the results of empirical research to set out the key phenomena that a theory of language acquisition must capture.

In the rest of this article, we introduce the problem of language acquisition in general terms, as a problem of inductive learning, and outline certain general puzzles concerning how learning of this type is possible. We then consider a range of specific formal analyses of aspects of the learning problem and we shall see that different idealizations appear to support very different qualitative conclusions about the nature of language acquisition. We shall, moreover, attempt to connect the discussion of formal modeling work with empirical constraints, qualitative theoretical analysis and computational modeling, emphasizing that formal models of language acquisition should be integrated with the wider scientific problem of understanding how children acquire language.

Language Acquisition as Induction

It has become standard to view the problem facing the child in the following terms. Language is governed by a highly complex set of regularities; the child is exposed to a finite set of examples of linguistic stimuli

that conform to these regularities; the goal of the child is to infer the regularities; these regularities then underpin the successful learner's generation of language in conformity with these regularities, so that the output of the successful learner can serve as input to future learners. In this way, language can be propagated from generation to generation.

This perspective sees the child's objective as, in part, theoretical: a key goal of the child is to infer the regularities of natural language from their instances. This view is an instance of the more general problem of theory-induction. Given data of whatever kind, whether linguistic, astronomical, or chemical, the task is to infer a theory of the domain in question, from observations of data from that domain. This general problem of theory induction thus immediately invites formal analysis, independent of the specifics of language acquisition.

A well-known result in the philosophy of science and statistics seems to yield a disconcertingly negative conclusion. The result is that theories are underdetermined by any finite quantity of data: that is, for any finite body of data, there will be infinitely many theories that are compatible with that data but that diverge arbitrarily when applied to non-observed data. How then, can a language learner pin down the correct regularities from a finite sample of language, so that the learner can generalize freely and creatively in generating new language? There is a range of possible responses to this query, focusing on, among other things, the available linguistic input, innate constraints, or the criterion of successful learning.

Regarding available linguistic input, perhaps the child has access to additional sources of empirical information that help pin down the correct regularities in the language. For example, perhaps the child receives and is able to use so-called 'negative evidence' – invalid linguistic inputs, somehow signaled as such (Brown and Hanlon, 1970). Or, somewhat implausibly, perhaps the child somehow has access to explicitly stated rules of linguistic correctness, as is typical in the instruction of second language learners. Or alternatively, it may be suggested that the connection between the structure of linguistic inputs and their meanings provides a rich set of additional constraints, and so on.

Regarding innate constraints, perhaps the child does not learn certain aspects of language from experience at all, but has an innate preference ordering over possible grammars of the language, and that it chooses the most preferred of these that is compatible with the current linguistic data (Chomsky, 1965). Or perhaps certain universal principles of grammar are innately fixed, and hence will be evident in all human languages, and the child merely needs to throw a number of switches during the acquisition process in order to choose the correct grammar (Chomsky, 1981).

Finally, regarding the criterion of successful learning, we might ask whether learners really do agree on the regularities in the language at all; or whether they may have different characterizations of these regularities, which merely happen to agree (mostly) in practice.

For each of these proposals, we can usefully ask complementary empirical and formal questions: What is the empirical evidence that this sort of information, constraint, or learning criterion is applicable to the child? And how would any such proposal modify the formal learning problem? We shall consider a selection of issues concerning the formal learning problem, below.

Do Learners Really Converge on the Same Regularities?

A slightly stronger result than the under-determination result mentioned above is that, even if we fix the complete (typically infinite) set of data over which our theory is to operate, there will be infinitely many ways of capturing the regularities in that domain (clearly the precise statement of this kind of result depends on how we use 'regularity'). For example, consider the infinite set of sentences generated by a phrase structure grammar. There will be infinitely many other phrase structure grammars that generate precisely the same sentences (just observe the indefinite number of ways in which rules and categories can be pointlessly duplicated; there are also much less trivial cases). It may turn out to be important that language learners can pick out some 'generatively equivalent' grammars rather than others. For example, some grammars may relate more transparently with semantics, or be easier to process. But the field of formal of language acquisition typically ignores the question of choosing between equivalent grammars.

Let us focus instead on the question of whether learners agree on overt linguistic data. An immediate issue concerns the nature of the linguistic data on which we evaluate any such agreement. One viewpoint, which can be traced to pre-Chomskyan linguistics, is that learners agree behaviorally – i.e., they treat linguistic inputs in the same way and tend to produce linguistic outputs with the same regularities. An aspect of this viewpoint is that the sentences that matter are those that are actually encountered. It seems natural, accordingly, to view language acquisition as a statistical problem, in which the learner must

agree on new cases after exposure to a sample from a statistical distribution. We shall see that formal methods from statistics can, indeed, be recruited to analyze this idealization of the language acquisition problem and that this viewpoint connects to recent work in corpus linguistics, computational linguistics, and psycholinguistics (Bod, 2003).

Since Chomsky (1965), however, there has been a considerable move away from this statistical perspective. The primary data for grounding linguistics theory has been presumed to be grammaticality (and other acceptability) judgments – and these judgments appear to be reliable far outside the realm of actually produced sentences. For example, outside linguistic discussion, the probability of encountering "Colorless green ideas sleep furiously" is infinitesimal; but arguably people agree that it is grammatically acceptable. Conversely, there are many things that people say, due to production errors, that the learner must reject, despite their statistical prevalence.

The language acquisition problem looks alarmingly difficult from this point of view, because the sample of sentences to which the child is exposed may differ considerably from that over which adult linguistic knowledge (as evidenced in grammaticality judgments) appears to reign. Moreover, the learner cannot, it appears, with any certainty, rely on helpful statistical regularities in the input, as these may reflect accidental and linguistically irrelevant features of the input. This perspective on the learning problem can be addressed using methods, not from statistics, but from a formal theory of identification in the limit (Gold, 1967).

Language Learning in the Limit

Consider the goal of learning which sentences are acceptable in a language, and which are not. Suppose that sentences (positive evidence) and non-sentences (negative evidence) are presented in an indefinitely long input corpus. Suppose that, after each successive sentence, the learner makes a 'current best guess' concerning the difference between sentences and non-sentences of the language. Under what conditions is it possible for the learner to find, eventually, a correct characterization of difference between sentences and non-sentences (to 'identify') the language, and to stick with this characterization however much further corpus of the language is encountered? This type of question is addressed by the theory of learning in the limit, invented by Gold (1967), and developed in a rich subsequent literature (Jain *et al.*, 1999; Osherson *et al.*, 1985).

Note that learnability in the limit does not require that the learner can announce when learning has succeeded, only that it *should* ultimately succeed. That is, the learner will get 'stuck' eventually, when it knows the language, but it may not know that it *has* got stuck. To see why this matters, consider the problem of learning one of the set of finite languages, for a corpus of positive data only, with the guarantee that every sentence will appear eventually (although arbitrarily late in the corpus). If the learner simply numerates sentences as it encounters them, then it will identify the language, once all sentences have been encountered, but it will not be possible to announce success, because the learner has no way of knowing that a further sentence may appear later on.

What conclusion can be derived from analysis of this kind? This is not a straightforward question to answer, because of the vast range of specific problems that can be studied (concerning properties of the corpus, the class of languages from which the learner selects, whether identification needs to be exact or approximate, and so on). Nonetheless, one conclusion from this work has entered linguistic and psychological folklore – that identifying infinite languages from positive linguistic data alone is problematic. As we have mentioned, there are many specific assumptions that can be used in studying language identification in the limit; here we sketch an informal argument that applies in a wide range of settings.

Before getting to the negative result, let us start with a positive case. Suppose that the set of 'possible' languages contains all and only finite languages (i.e., finite sets of sentences, however large, composed of some basic symbolic elements, e.g., phonemes or words). And that every corpus of a language will contain every sentence in that language eventually, and that there are no other constraints on what a corpus may look like (i.e., it can be as 'perverse' as you like). Consider the following, trivial, learning method, that we have mentioned already: at each point in the corpus, guess that the language consists of all and only those sentences you have heard so far. Thus, every time a new sentences arises, we add it to our current hypothesis; otherwise, we leave the hypothesis as it is. This method will learn any finite language 'in the limit' – by hypothesis, every sentence in the target language turns up eventually; once they have all occurred, the correct hypothesis is stated, never to be retracted. The learner never knows that learning has succeeded – because another sentence could occur at any point; but nonetheless, after a certain point in the corpus, the language will be correctly, and permanently, identified.

Now suppose that we add a single infinite language, I, to the picture. The previous learning method will never identify this language, as it will only

postulate (increasingly large) finite languages. But it turns out that **no** learning method will reliably identify the set of all finite languages, together with *I* (at least, with no further assumptions). Let's sketch a proof by *reductio ad absurdum*. Suppose that this set of languages *is* identifiable by a learner.

Consider a finite 'prefix' of our potentially infinite corpus (i.e., some finite initial chunk), which leads the learner to hypothesize the infinite language, *I*. This corpus is finite, and hence is compatible with all finite languages containing the finite set of items in the corpus, including finite subsets of *I*. It **could** turn out that the target language is one of these subsets. If so, by assumption, the learner will be able to identify it – hence, there will be continuations of that corpus (indeed, infinitely many) that will lead the learner to reject *I* and hypothesize this finite language. So, whenever the learner is fixated on an infinite language, the corpus may always continue so as to 'bounce' it back to postulating a finite language, which is a subset of *I*.

Conversely, consider any finite prefix of a corpus that leads the learner to postulate a finite language that is a subset of *I*. It is of course possible that the true language is *I*, and that as the corpus continues, the learner will realize this truth (by assumption, the learner identifies all languages), and postulate *I*. So, whenever the learner is fixated on a finite language, the corpus may always continue so as to 'bounce' it back to postulating the infinite language, *I*.

Combining these two observations, we can see that it is possible to construct a corpus that will make any learning method bounce infinitely often between *I* and (different) finite subsets of *I*, and never settle. This corpus will, as it happens, only be compatible with *I* (every finite subset of *I* will be rejected); but the learner will never identify *I*, but will vacillate endlessly between finite languages and the infinite language, *I*.

The details of arguments like this, even when described intuitively, are not easy to follow, as the reader may attest (and the conditions of validity of this argument depends on our specific formal assumptions, which have been neglected here). But there is a general moral that is more intuitive: learning infinite languages from positive evidence is difficult. Making any jump from a finite corpus to an infinite corpus is risky, because if the correct language is smaller, it will be difficult to realize this (the mere non-occurrence of a sentence is no evidence that it does not exist; after all, in an infinite language, the overwhelming majority of sentences do not occur, in any finite section of a corpus). So this caution might suggest a conservative approach, of choosing the smallest language set that fits the prefix of the corpus that has been seen so far. But this limitation will never work for learning infinite languages, because (a) the smallest such language fitting the corpus is always finite; (b) even if we disallow finite languages, for any infinite language containing some set of sentences, there will be a smaller infinite language that also contains that set – and hence there is no smallest such infinite set on which we may alight (except given rather strict assumptions about the class of allowable languages).

How Is Language Acquisition Possible?

Negative Evidence

A natural conclusion to draw from this line of argument is that, under reasonable conditions, infinite languages cannot be learned from positive data – and hence that natural language cannot be learned from positive data alone. With only positive data, there seems to be no way to eliminate over-general grammars that postulate that the language contains more sentences than it does.

To prune back over-general grammars would, though, be greatly assisted by the presence of negative data, i.e., non-sentences, labeled as such. Mathematical analysis does, indeed, show that an appropriately comprehensive stream of negative data can allow infinite languages to be identified in a broad range of cases where positive data alone is insufficient. It seems prima facie plausible that negative evidence might be available and used: for example, one can imagine that a child with an over-general grammar will thereby produce anomalous sentences, leading to correction by parents; incomprehension, rephrasing, puzzlement, or some other indication that the sentence is not correct. The theoretical significance of negative evidence has focused considerable attention on the empirical question of how far children have access to, and can use, such evidence – the majority view appears to be that language acquisition can occur normally where no such evidence is available.

A Finite Set of Languages

If negative evidence does not explain how infinite natural languages can be learned, a natural alternative is to suggest that there are only a finite number of possible natural languages – so that, as we saw above – the correct language can be identified, given positive data alone. This viewpoint has been dominant in linguistics since the 1980s. Chomsky's principles and parameters program proposes that natural languages differ only on a finite number of parameters, each of which has a finite set of discrete values – thus, superficial lexical variation aside, there are essentially a

finite number of possible languages, and the principles that are universal to all natural languages are not learned at all, but are innately specified.

Learning to set parameters is particularly straightforward if there are triggers in the linguistic input that can be detected independently for each parameter. In practice, however, this awareness may not always be straightforward, because linguistic input can only be viewed as evidence for a particular parameter value (e.g., that the language allows subject pronouns to be omitted), given a particular *interpretation* of the linguistic input. An uninterpreted stream of sounds cannot, for example, provide evidence about whether a language does, or does not, allow subject pronouns to be omitted. The problem of learning from triggers has been the subject of sophisticated analysis (Gibson and Wexler, 1994; Berwick and Niyogi, 1996), but it is clear that the problem of learning parameters from corpora of real linguistic data, by finding triggers or by other means, is extremely challenging.

A related line of formal research has concerned the degree to which languages can be acquired from exposure to a specific subset of the language. Natural languages allow clauses to be recursively embedded within each other arbitrarily often – yet such embeddings are rather rare in the child's input. Wexler and Culicover (1980), working in a transformational framework, proved that, under certain assumptions, a child exposed to base- and surface-structure pairs for sentences of the language with up to two embeddings (e.g., John believed [that Bill thought {the cat had been fed}]) could learn the entire language. This concept was known as degree-2 learnability. Using a different formal setting, Morgan (1986) showed that, again under specific assumptions, one level of embedding was sufficient: degree-1 learnability. Lightfoot (1991) has argued for degree-0 learnability, essentially on the grounds that main clauses, with no embeddings, are sufficient to set the finite number of parameters required to identify each natural language successfully.

Stronger Assumptions about Positive Data

A very different way in which language acquisition can be recast to appear more tractable is by making stronger restrictions on the corpora that children receive. We have so far assumed only that the corpus for a language eventually includes any sentence of the language, and no non-sentences. But very much stronger assumptions may be realistic. Indeed, an early result by Horning (1969) showed that languages generated by a probabilistic context-free phrase structure grammar could, with high probability, be identified to an arbitrarily good approximation given sufficient positive data. The critical assumption Horning makes is that sentences are chosen by sampling independently from a probability distribution, so that each sentence has the same probability of being sampled at any time. This means that, with high probability, a corpus with a large sample of sentences will be a reasonably reliable indication of the properties of the rest of the same. In particular, this assumption allows the learner to prune over-general grammars, even in the absence of negative evidence. To take an extreme example, a grammar that ignored agreement between noun and verb might imply, say, that there are roughly twice as many sentences in English than there really are. For example, for each sentence such as *John runs*, according to this over-general grammar, there is an equally viable sentence *John run*. Thus, according to this over-generality, the probability that a sentence happens, by chance, to exhibit 'correct' agreement (*John runs*) is about one-half. But these odds mean that the probability that a corpus of, say 100 English sentences, would happen to contain just sentences with 'correct' agreement would be the infinitesimally tiny 2^{-100}. Hence this over-general grammar can be decisively rejected. Similar assumptions can be used to reject grammars that are much less over-general – although, of course, more data is required to eliminate these with a reasonably high level of confidence.

It turns out, intriguingly, that it is possible to prove similar results with much more modest assumptions about the language that learners encounter. Perhaps the most surprising results of this kind stem from a remarkable theorem, due to Solomonoff (1978), in the context of the general problem of inductive inference. Solomonoff considered the question of predicting the next item in a sequence that can be determined by any computation whatever, mixed with any amount of random noise. At each point, the learner's goal is to provide a probability distribution over possible next items in the sequence; this predicted distribution is then compared with the true distribution (as defined by the process actually producing the sequence). Solomonoff considered an 'ideal' learner, that finds the shortest computer program. This learner starts by generating the current sequence and predicts according to the next item produced by the program (more precisely, the ideal learner considers a weighted sum of predictions of such programs, where the shortest are weighted most heavily). This approach corresponds to learning using a principle of simplicity, of a kind reminiscent of, though not identical to, simplicity measures over grammars considered in early views of language acquisition with the

framework of generative grammar (Chomsky, 1975). The key result is that the sum-squared error between the predicted and true probability distributions, summed up over the entire infinite sequence, has a finite sum – proportional to the complexity of the process of generating the language. This means that, even with these minimal computational restrictions on the nature of the corpus (and no additional restrictions on the form of the grammar whatever), predictions become arbitrarily good, with enough corpus (strictly, this result holds only with overwhelming probability, rather than with complete certainty).

This and related results about prediction can be adapted to more directly interesting linguistic ends. It can be shown that an ideal learner can, under these conditions, learn to make arbitrarily good grammaticality judgments, produce language, and even to learn the mapping between form and meaning given an unlimited sample of form-meaning pairs (Chater and Vitányi, 2004).

From Learnability to Theories of Language Acquisition

Theorems about learnability typically make rather abstract assumptions about the problem of language acquisition. This level of abstraction makes the mathematics tractable; it makes it possible to place bounds (typically upper bounds) on what can be learned, given certain assumptions – and these bounds must be respected if those assumptions are supplemented with greater detail. The approach also has the advantage of crystallizing otherwise informal debates concerning learning, concerning, for example, how far language can be learned from positive data, or the extent to which learning must be guided by innate constraints. There are, moreover, many further issues, that we have not touched on in this brief article, that learnability results can address, including how the non-grammatical utterances, which are widespread in the child's input, affect learning; how much linguistic material is required to learn different aspects of language; whether there are advantages for the learner in receiving simplified linguistic input.

These abstract analyses are complementary to detailed research on how children's language develops, the input available to the child and the aspects of that input the child is able to exploit, and possible mechanisms by which language acquisition may occur. Building a theory of how children acquire language requires providing a highly specific model of the computational learning mechanisms available to the child, and showing how it produces the pattern of observed linguistic development, given the linguistic, and non-linguistic, inputs available to children. But achieving such a synthesis is far beyond the scope of present research, except for extremely restricted aspects of language (e.g., learning specific aspects of phonology, morphology, or learning crude syntactic categories). Learnability results, by abstracting from such details, allow some insights into what is required for the language as a whole to be learned, and allow progress to be made, even in the absence of detailed empirical constraint. Yet the very abstraction that makes learnability theory tractable also implies that its results should be treated with caution, when applied to theories of language acquisition. The results of learnability may be too weak (because the child has recourse to much richer linguistic or non-linguistic input, or due to innate constraints), or too strong (because the child does not exploit information that is potentially available). It may be hoped, however, that mathematical results on learnability, and increasingly detailed empirical work, may eventually converge to provide richer and more realistic theoretical models of how children acquire language.

Formal Semantics

G Chierchia, Universita degli Studi di Milano-Bicocca, Milan, Italy

Introduction

Semantics, in its most general form, is the study of how a system of signs or symbols (i.e., a language of some sort) carries information about the world. One can think of a language as constituted by a lexicon (an inventory of morphemes or words) and a combinatorial apparatus according to which complex expressions, including, in particular, sentences, can be built up. Semantics deals with the procedures that enable users of a language to attach an interpretation to its arrays of symbols. Formal semantics studies such procedures through formally explicit mathematical means.

The history of semantics is nearly as long and complex as the history of human thought; witness, e.g., the early debates on the natural vs. conventional character of language among the pre-Socratic philosophers. The history of formal semantics is nearly as daunting as it is intertwined with the development of logic. In its modern incarnation, it is customary to locate its inception in the work of logicians such as Frege, Russell, and Tarski. A particularly important and relatively recent turning point is constituted by the encounter of this logico-philosophical tradition with structural and generative approaches to the study of human languages, especially (though by no means exclusively) those influenced by N. Chomsky. The merger of these two lines of research (one brewing within logic, the other within linguistics), has led formal semantics to become a central protagonist in the empirical study of natural language. The research paradigm that has emerged has proven to be quite fruitful, both in terms of breadth and depth of results and in terms of the role it is playing in the investigation of human cognition. The present work reviews some of the basic assumptions of modern formal semantics of natural language and illustrates its workings through a couple of examples, with no pretence of completeness.

Semantics vs. Lexicography

One of the traditional ideas about semantics is that it deals with the meaning of words. The main task of semantics is perceived as the compilation of dictionaries (semantics as lexicography). To this, people often add the task of investigating the history of words. Such a history can teach us about cultural development. One might even hope to arrive at the true meaning of a word through its history. Compiling dictionaries or reconstructing how particular words have changed over time are worthy tasks; but they are not what formal semantics is about. Lexicography, philology, and related disciplines vs. semantics as conceived here constitute complementary enterprises. They all, of course, deal with language. But the main goal of semantics is to investigate how we can effortlessly understand a potential infinity of expressions (words, phrases, sentences). To do that, we have to go beyond the level of single words.

It may be of use to point to the kind of considerations that have led semantics to move the main focus of investigation away from single word meanings and their development. For one thing, it can be doubted that word histories shed light on how words are synchronically (i.e., at a given point in time) understood and used. People use words effectively in total ignorance of their history (a point forcefully made by one of the founding fathers of modern linguistics, namely F. de Saussure). To make this point more vividly, take the word *money.* An important word indeed; where does it come from? What does its history reveal about the true meaning of money? It comes from Latin *moneta*, the past participle feminine of the verb *moneo* 'to warn/to advise.' *Moneta* was one of the canonical attributes of the Roman goddess Juno; *Juno moneta* is 'the one who advises.' What has Juno to do with money? Is it perhaps that her capacity to advise extends to finances? No. It so happens that in ancient Rome, the mint was right

Introduction

Semantics, in its most general form, is the study of how a system of signs or symbols (i.e., a language of some sort) carries information about the world. One can think of a language as constituted by a lexicon (an inventory of morphemes or words) and a combinatorial apparatus according to which complex expressions, including, in particular, sentences, can be built up. Semantics deals with the procedures that enable users of a language to attach an interpretation to its arrays of symbols. Formal semantics studies such procedures through formally explicit mathematical means.

The history of semantics is nearly as long and complex as the history of human thought; witness, e.g., the early debates on the natural vs. conventional character of language among the pre-Socratic philosophers. The history of formal semantics is nearly as daunting as it is intertwined with the development of logic. In its modern incarnation, it is customary to locate its inception in the work of logicians such as Frege, Russell, and Tarski. A particularly important and relatively recent turning point is constituted by the encounter of this logico-philosophical tradition with structural and generative approaches to the study of human languages, especially (though by no means exclusively) those influenced by N. Chomsky. The merger of these two lines of research (one brewing within logic, the other within linguistics), has led formal semantics to become a central protagonist in the empirical study of natural language. The research paradigm that has emerged has proven to be quite fruitful, both in terms of breadth and depth of results and in terms of the role it is playing in the investigation of human cognition. The present work reviews some of the basic assumptions of modern formal semantics of natural language and illustrates its workings through a couple of examples, with no pretence of completeness.

Semantics vs. Lexicography

One of the traditional ideas about semantics is that it deals with the meaning of words. The main task of semantics is perceived as the compilation of dictionaries (semantics as lexicography). To this, people often add the task of investigating the history of words. Such a history can teach us about cultural development. One might even hope to arrive at the true meaning of a word through its history. Compiling dictionaries or reconstructing how particular words have changed over time are worthy tasks; but they are not what formal semantics is about. Lexicography, philology, and related disciplines vs. semantics as conceived here constitute complementary enterprises. They all, of course, deal with language. But the main goal of semantics is to investigate how we can effortlessly understand a potential infinity of expressions (words, phrases, sentences). To do that, we have to go beyond the level of single words.

It may be of use to point to the kind of considerations that have led semantics to move the main focus of investigation away from single word meanings and their development. For one thing, it can be doubted that word histories shed light on how words are synchronically (i.e., at a given point in time) understood and used. People use words effectively in total ignorance of their history (a point forcefully made by one of the founding fathers of modern linguistics, namely F. de Saussure). To make this point more vividly, take the word *money.* An important word indeed; where does it come from? What does its history reveal about the true meaning of money? It comes from Latin *moneta*, the past participle feminine of the verb *moneo* 'to warn/to advise.' *Moneta* was one of the canonical attributes of the Roman goddess Juno; *Juno moneta* is 'the one who advises.' What has Juno to do with money? Is it perhaps that her capacity to advise extends to finances? No. It so happens that in ancient Rome, the mint was right

next to the temple of Juno. So people metonymically transferred Juno's attribute to what was coming out of the mint. A fascinating historical fact that tells us something as to how word meanings may evolve; but it reveals no deep link between money and the capacity to advise. This example is not meant to downplay the interest of historical investigations on word meanings; it is just an illustration of how linguistic history affects only marginally the way in which a community actually understands its lexicon.

There is a second kind of consideration suggesting that the scope of semantics cannot be confined to the study of word meanings. Do words in isolation have clearly identifiable meanings? Take any simple word, say the concrete, singular, common noun *dog*. What does it mean? Some possible candidates are: the dog-kind, the concept of dog, the class of individual dogs. . . . And the list can go on. How do we choose among these possibilities? Note, moreover, that all these hypotheses attempt to analyze the meaning of the word *dog* by tacking onto it notions (kind, concept, class . . .) that are in and of themselves in need of explication. If we left it at that, we wouldn't go far. Looking at dictionary definitions is no big help either. If we look up the entry for *dog*, typically we will find something like:

(1) A highly variable carnivorous domesticated mammal (Canis familiaris) prob. descended from the common wolf.

Indeed, if someone doesn't know the meaning of the word *dog* and knows what *carnivorous* and *mammal* mean, then (1) may be of some practical help. But clearly to understand (1), we must rely on our understanding of whole phrases and the words occurring in them. Words which, in turn, need a definition to be understood. And so on, in a loop. This problem is sometimes called the problem of the circularity of the lexicon. To put it differently, (1) is of help only if the capacity to use and interpret language is already taken for granted. But it is precisely such capacity that we want to study.

The limitation of a purely word-based perspective on the investigation of meaning is now widely recognized. Frege summarized it in a nice motto: "only in the context of a sentence do words have meaning." His insight is that complete sentences are linguistic units that can sort of stand on their own (more so than any other linguistic units). They can, as it were, express self-contained thoughts. We are more likely, therefore, to arrive at the meaning of single words (and of phrases in between words and complete sentences) via a process of abstraction from the contribution that words make to sentence meaning, rather than the other way around. This is so because sentence meaning is somehow more readily accessible (being, as it were, more complete) than the meaning of words in isolation.

These are some reasons, then, why the perspective of modern semantics is so different from and complementary to lexicography and philology; such perspective is much more directly tied to the investigation of the universal laws of language (language universals) and of the psychological mechanisms underlying such laws. Understanding the function, use, etc., of a single word presupposes a whole, complex cognitive apparatus. It is, therefore, an arrival point more than a starting point. It seems thus reasonable to start by asking what it is to understand a sentence.

The main thesis we wish to put forth is that to understand a sentence involves understanding its relations to the other sentences of the language. Each sentence carries information. Such information will be related to that of other sentences while being unrelated to that of yet others. In communicating, we rely on our spontaneous (and unconscious) knowledge of these relations.

The Notion of Synonymy and Its Problems

Imagine watching a Batman movie in which the caped hero fights the Riddler, one of his eternal foes. The Riddler has scattered around five riddles with clues to his evil plans. Batman has managed to find and solve four of them. We could report this situation in any of the following ways:

(2a) Batman has found all of the five clues but one.
(2b) Batman has found four out of the five clues.
(2c) Four of the five clues have been found by Batman.

These sentences are good paraphrases of each other. One might say that they have roughly the same information content; or that they describe the same state of affairs; or that they are (nearly) synonymous. (I will be using these modes of speaking interchangeably.) To put it differently, English speakers know that there is a tight connection between what the sentences in (2a), (2b), and (2c) mean. This is a kind of knowledge they have *a priori,* i.e., regardless of what actually goes on. Just by looking at (2a) vs., say, (2b) and grasping what they convey, we immediately see that they have roughly the same informational content.

This is what we mean when we say that understanding a sentence involves understanding which other sentences count as good paraphrases and which don't. Thus, knowing a language is to know which sentences in that language count as synonymous. Semantics is (among other things) the study of synonymy. Two synonymous sentences (and, more generally, two synonymous expressions) can always

be used interchangeably. This last informal characterization can be turned into a precise definition along the following lines.

(3a) Suppose one utters any complex expression α containing a subexpression A. If one can replace in A α with a different expression β, without changing the overall communicative import of A, then α and β are synonymous.

(3b) α is synonymous with β = in the utterance of any expression A containing α, α can be replaced with β without changing the communicative import of the utterance (*salva significatione*).

For example, in uttering (2a) (our A), we can replace the subcomponent that comes after *Batman has found__* namely *all of the five clues but one* (our α) with *four out of the five clues* (our β) and convey exactly the same information. Hence, these two expressions must be synonymous (and, in fact, so are the whole sentences).

This looks promising. It paves the way for the following setup for semantics. Speakers have intuitions of whether two expressions can be replaced with each other while keeping information content unchanged. For any two sentences α and β, they spontaneously know whether they can be substituted for each other (i.e., whether β can be used to paraphrase α). Because the sentences of a language are potentially infinite, it is impossible for speakers to memorize synonymous sentences one by one (for that clearly exceeds what our memory can do). Hence, they must recognize synonymy by rule, by following an algorithm of some sort. The task of semantics, then, becomes characterizing such an algorithm.

There is a problem, however. Sameness of communicative import is a more or less thing, much like translation. In many contexts, even sentences as close as those in (3a) and (3b) could not be replaced felicitously with each other. Here is a simple example. The discourse in (4a) is natural and coherent. The one in (4b) much less so:

(4a) Batman has found all of the five clues but one, which is pinned on his back.

(4b) ?? Batman has found four out of the five clues, which is pinned on his back.

(modeled after a famous example by B. Partee)

Clearly in (4a) we cannot replace *Batman has found all of the five clues but one* with *Batman has found four out of the five clues* while keeping unaltered the overall communicative effect. This means that if we define synonymy as in (3a) and (3b), then (2a) and (2b) cannot be regarded as synonymous after all. Yet they clearly share a significant part of their informational content. What *is* it that they share?

In fact, it has been argued that if (3a) and (3b) are how we define synonymy, then there simply are no two sentences that qualify as such. Here is a classical argument that purports to show this (based on Mates (1950)). Take the following two sentences:

(5a) Billy has a dog.

(5b) Billy has a highly variable carnivorous domesticated mammal prob. descended from the common wolf.

Are these two sentences synonymous? Hardly. They are clearly semantically related. But they surely do not have the same communicative import. Nor can one replace the other in every context. For example, (5a) could describe a true state of affairs, while (5b) might not:

(6a) Molly believes that Billy has a dog.

(6b) Molly believes that Billy has a highly variable carnivorous domesticated mammal prob. descended from the common wolf.

This shows that in contexts like *Molly believes that __* we cannot simply replace a word with its dictionary definition. And if dictionary definitions don't license synonymy, then what does?

The problem can be couched in the following terms. Any normal speaker of English perceives a strong semantic connection among the sentences in (2a), (2b), and (2c), or (4a) and (4b). So strong that one might feel tempted to talk about synonymy. Yet when we try to make the notion of synonymy precise, we run into serious problems. Such a notion appears to be elusive and graded (a more or less thing); so much so that people have been skeptical about the possibility of investigating synonymy through precise, formal means.

A fundamental breakthrough has been identifying relatively precise criteria for assessing semantic relations. The point is that perfect synonymy simply does not exist. No two sentences can be always replaced with each other. The notion of synonymy has to be deconstructed into a series of more basic semantic relations. We need to find a reliable source for classifying such relations, and, we will argue, such a source lies in the notions of truth and reference. Consider the sentences in (2a), (2b), and (2c) again. Assume that the noun phrase *the five clues* in (2a) and (2b) refer to the *same* clues (i.e., we are talking about a particular episode in a particular story). Then, could it possibly happen that say (2a) is true and (2b) false? Evidently not: no one in his right mind could assert (2a) while simultaneously contending that (2b) is false. If (2a) is true, (2b) also must be true. And, in fact, vice versa: if (2b) is true, then (2a) also must be. When this

happens, i.e., when two sentences are true in the same set of circumstances, we say that they have the same truth conditions.

Notice that sameness of truth conditions does not coincide with or somehow require sameness of communicative import (too elusive a notion), nor substitutivity in any context whatsoever (a condition too difficult to attain). Our proposal is to replace such exceedingly demanding notions with a series of truth-based notions, while keeping the same general setup we sketched in connection with synonymy: for any pair of sentences, speakers have intuition about whether they are true under the same conditions or not. They can judge whether they are true in the same (real or hypothetical) circumstances or not. Because the sentences of our language are infinite, this capacity must be somehow based on a computational resource. Speakers must be able to compare the truth-conditions associated with sentences via an algorithm of some sort. The task of semantics is to characterize such an algorithm. The basic notion changes (synonymy is replaced with sameness of truth conditions), but the setup of the problem stays the same.

Truth and Semantic Competence

Let us elaborate on the proposal sketched at the end of the previous section. Information is transmitted from one agent to another (the 'illocutionary agents') in concrete communicative situations ('speech acts'). No two such situations are alike. And consequently, no two pieces of information that are transmitted through them are alike. In *Groundhog Day,* a movie with the actor Bill Murray, the protagonist gets trapped into going through the same day over and over. He wakes up and his day starts out in the same way (with the alarm clock ringing at 7 a.m. on groundhog day); as he walks outside, he meets the same waitress who greets him in the same way ("weather so-so, today"). Yet this sentence, though being the same day after day, and being uttered in circumstances as identical as they can conceivably be, clearly conveys a different sense or information unit on each occasion of its use (the hearer going from noticing that something is fishy about this verbatim repetition, to the painful discovery of the condemnation to live through groundhog day for eternity).

Ultimately, we want to understand how communication takes place. But we cannot nail down every aspect of a speech act, just as we cannot know (not even in principle, I believe) every aspect of the physical or mental life of a particular human being. At the same time, while speech acts are unique events, there is much that is regular and invariant about them; that is what can be fruitfully investigated. One family of such invariants concerns form: similar sound patterns may be used in different speech acts. Another family of invariants concerns content: similar states of affairs may be described through a variety of expressions. The notion of truth is useful in describing the latter phenomenon. A pair of sentences may be judged as being necessarily true in the same circumstances. This is so, for example, for (5a) vs. (5b). Yet, such sentences clearly differ in many other respects. One is much more long-winded than the other; it uses rarer words, which are typical of high, formal registers. So in spite of having the same truth conditions, such sentences may well be used in different ways. Having the same truth condition is generally regarded as a semantic fact; being able to be used in different ways is often regarded as a pragmatic fact. While this gives us a clue as to the role of these two disciplines (both of which deal with meaning broadly construed), the exact division of labor between semantics and pragmatics remains the object of controversy.

Truth conditions are a tool for describing semantic invariants, structural regularities across communicative situations. Whenever I utter a declarative sentence, I typically do so with the intention to communicate that its truth conditions are satisfied (which of course raises the question of nondeclaratives, emotive expressions, and the like; see for example textbooks such as Chierchia and McConnell-Ginet (2000) or Heim and Kratzer (1998); cf. also Kratzer (1999) for a discussion of relevant issues). Truth conditions depend on the reference (or denotation) of words and the way they are put together, i.e., they are compositionally projected via the reference of words (or morphemes). If I say to you, as we are watching a movie, "Batman has found all of the five clues but one," you understand me because you sort of know (or guess) who Batman is, what sort of things clues are, what finding something is, what number the word *five* refers to; you also understand the "all … but …" construction. The reference/denotation of words is set (and is modified, as words may change their denotation in time) through use, in complex ways we cannot get into within the limits of the present work. The denotation of complex expressions (e.g., of a verb phrase such as [$_{VP}$*found five clues*] and truth conditions of sentences) are set by rule (the semantic component of grammar). Semantic rules presumably work like syntactic rules: they display variation as well as a common core, constitutive of universal grammar. Insofar as semantics is concerned, what is important for our purposes is that truth conditions can be compositionally specified. This paves the way for an algorithmic approach to meaning. We already remarked that sentences are formed by

composing morphemes together via a limited number of syntactic operations. So to arrive at the truth condition of an arbitrary sentence, we can start by the contribution of the words (their reference). Then, for each way of putting words together, there will be a way of forming the reference of complex expressions, and so on until we arrive at the truth condition of the target sentence.

So far, we have discussed sentences that have the same truth conditions (such as those in (2a), (2b), and (2c)); but this is not the only semantic relation that can be characterized in terms of the notion of truth. Consider the following examples.

(7a) Every Italian voted for B — a'. Most Italians voted for B.
(7b) Leo voted for B — b'. Leo voted for B.

Sentence (7a) is related to (7b) in a way that differs from the relation between (7a') vs. (7b'). Here is the difference. If (7a) is true, and Leo is Italian, then (7b) has to be true, too; this is clearly not so for (7a') vs. (7b'): (7a') may be true without (7b') being true. If whenever A is true, B also must be, we say that A *entails* B (B's meaning is part of of A's meaning). Two sentences with the same truth conditions entail each other (i.e., they hold a symmetric relation); when entailment goes only one way (as from (6a) to (6b)), we have an asymmetric relation.

Entailment is pervasive. Virtually all semantic intuitions are related to it. As an illustration, consider the pair of sentences in (8a) and (8b).

(8a) John promised Bill to take him to the station.
(8b) John ordered Bill to take him to the station.

Pronouns, like *him* in (8a) and (8b), take their denotation from the context; they can take it from the extra linguistic context (a person salient in the visual environment, a person the speaker points at, etc.) or from the linguistic context (e.g., from NPs that occur in the same discourse; *John* or *Bill* in (8a) and (8b)); one widespread terminology is to speak of *indexical* uses in the first case and of *anaphoric* uses in the second. We can conceptualize this state of affairs by viewing pronouns as context-dependent items, incomplete without pointers of some sort. Now we shall focus on the anaphoric interpretation of (8a) vs. (8b).

(9a) John promised Bill that John would take Bill to the station.
(9b) John ordered Bill that Bill should take John to the station.

These appear to be the only options. That is to say, sentence (8a) cannot convey something like 'John promised Bill that Bill should take John to the station.' The point of this example is that we have intuitions that govern how the denotation of a pronoun is to be reconstructed out of contextual clues; such intuitions tell us that (8a) and (8b), though structurally so similar, allow for a distinct range of interpretive options. At the basis of intuitions of this sort, we again see entailment at work: on its anaphoric construal, (8a) entails (9a).

Another important set of truth-based semantic relations are presuppositions. Consider the contrast between the sentences in (10a) and (10b).

(10a) Fred stole the cookies.
(10b) It was Fred who stole the cookies.

There is a noticeable semantic contrast between (10a) and (10b). How can we characterize it? Clearly the two sentences are true in the same circumstances (they entail each other). Yet they differ semantically. Such a difference can be perhaps caught by looking at what happens by embedding (10a) and (10b) in a negative context.

(11) So, what happened this morning?
(11a) Everything went well. Fred didn't steal the cookies; he played with his toys.
(11b) ?? Everything went well. It wasn't Fred who stole the cookies.

The answer in (11a) is natural. The one in sentence (11b) would sound more natural as an answer to

(12a) Who stole the cookies?
(12b) It wasn't Fred.

The difference between the question in (11) and the one in (12a) is that the latter (but not the former) tends to presuppose that cookies where stolen. In other terms, the situation seems to be the following. Both sentences in (10a) and (10b) entail:

(13) Someone stole the cookies.

If either (11a) or (11b) are true, then (13) must also be true. Furthermore, sentence (13) must be true for (10b) to be *denied* felicitously. The illocutionary agents must take for granted the truth of (13) to assert, deny, or otherwise use sentence (10b), as the naturalness of the following continuations for (13) illustrate:

(14) Someone stole the cookies . . .
(14a) It was Fred.
(14b) It wasn't Fred.
(14c) Was it Fred?
(14d) If it was Fred, he is going to get it . . .

This brings us to the identification of presupposing as a distinctive semantic relation: a sentence A presupposes B if the truth of B must be taken for granted

in order to felicitously assert, deny, etc., A. Presuppositions are quite important in language. So much so that there are distinctive syntactic constructions (such as those in (10b), known as cleft sentences) specifically keyed to them.

Let me illustrate the wealth of semantic relations and their systematic character by means of another example, which will bring us to the interface between semantics and pragmatics. Consider:

(15a) Who stole the cookies?
(15b) Fred looks mischievous.
(15c) Fred stole the cookies.

If to a question such as (15a), I reply with (15b), I do suggest/convey something like (15c). Sentence (15c) clearly is not part of the literal meaning of (15b) (however hard defining such a notion might be). Yet, in the context of the dialogue in (15a), (15b), and (15c), speakers will converge in seeing that (15c) is strongly suggested by (15b). Here, too, we have, thus, a systematic semantic intuition. The suggestion in (15c) can be retracted; that is, one can continue (15b) with '... but I know he didn't do it'. However, in the absence of such an explicit correction, illocutionary agents upon hearing (15b) will tend to infer (15c). This phenomenon has been studied by H. P. Grice (1989), who dubbed it implicature. His proposal is that it arises through interaction of the core meaning assigned to sentences by rule with principles that govern conversational exchanges. The basic idea is that for conversational exchanges to be successful they have to be basically cooperative acts; cooperating means that one sticks to relevant topics, one only gives information believed to be truthful, one gives no more and no less than what is relevant, etc. Applying this to the case at hand, in a situation in which question (15a) is topical, answering (15b) would seem to be blatantly irrelevant; the hearer, however, tends to interpret it as relevant and sets in motion an inferential process that tends to link it to some piece of information that does address the topical question; such a link is to be found with the help of the information available in the context to the illocutionary agents (e.g., in the common knowledge that if people commit a mischief, such as stealing cookies, they may well look mischievous, etc.). Thus, this type of semantic judgment (the implicature) appears to be best accounted for in terms of the interaction between grammar and general conditions on reasonable language use (that fall under the scope of pragmatics).

Sometimes it is not immediately clear whether something is a matter of conventionalized meaning or pragmatics. To illustrate, consider the oscillation in meaning of a word like *or*. It can be illustrated with the following examples. Consider first (16a):

(16a) If I got it right, either John or Mary will be hired.
(16b) If I got it right, either John or Mary but not both will be hired.

Normally, one tends to interpret (16a) as truth conditionally equivalent to (16b); i.e., the disjunction in (16a) is interpreted exclusively (as incompatible with the simultaneous truth of each disjunct). However, this is not always so. Contrast (16a) with (17a).

(17a) If either John or Mary are hired, we'll celebrate.
(17b) (?) If John or Mary (but not both) are hired, we'll celebrate.
(17c) If John or Mary or possibly both are hired, we'll celebrate.

The most natural interpretation of (17a) is not the exclusive one (namely (17b), which is somewhat odd pragmatically); rather it is the inclusive one, made explicit in (17c). (Notice that the emphatic word *either* is present both in (16a) and (17a); in spite of this, the interpretation of *or* shifts.) We might see in these phenomena a lexical ambiguity of disjunction. Words expressing disjunction, we may feel inclined to conclude, have a varying interpretation, as it happens with words such as *bank* or *lap* ('sit on my lap' vs. 'he swam three laps'). We may assume that such interpretations are always in principle available, but then we select the most suitable to the context of the speech act. While this seems *prima facie* possible, there are reasons to doubt it. In particular, true lexical ambiguities are resolved across languages (in Italian, there are two different words for the two senses of *lap*). Ambiguities are never universal. The meaning shift of *or*, *per contra*, seems to be universal: in every language disjunction appears to have a similar oscillation in meaning. A convincing case for two lexically distinct disjunctions, one exclusive, the other exclusive, has not been made (sometimes it has been proposed that Latin *vel* vs. *autem* is just that; for arguments against this, cf., e.g., Jennings (1994)). Moreover, other areas of the lexicon have been found that display a similar behavior (e.g., the number words). This strongly suggests that a different explanation for such behavior should be found. Grice himself has proposed that the phenomenon under discussion is to be accounted for in terms of the interaction between semantics and pragmatics. The idea is that the basic meaning of *or* is the inclusive one, as it is the most liberal interpretation; the exclusive construal arises as an implicature, i.e., a

pragmatic enrichment, albeit a generalized one. The advantage of this move is that it would explain the oscillation in meaning of disjunction without positing a covert ambiguity. We will come back to how the generalized implicature associated with *or* might come about in the later section "The Semantics/Pragmatics Interface".

Wrapping up, the picture that emerges is roughly the following. In using language, speakers display complex forms of spontaneous knowledge. They put together words in certain ways and not others. This is how knowledge of syntax manifests itself. They also accept certain paraphrases and not others, draw certain inferences and not others, etc. It turns out to be possible/useful to categorize the latter in three major families of semantic relations.

(18a) Entailment-based (entailment, mutual entailment, contradictoriness, analyticity, etc.)
(18b) Presupposition-based (presupposition, question/answer pairs, etc.)
(18c) Implicature-based (generalized implicature, particularized implicature, etc.)

All of them can be readily defined in terms of the notion of truth:

(19a) A entails B = for any conceivable situation s, if A is true in s, B is also true in s.
(19b) A presupposes B = to use A appropriately in a situation s, the truth of B must be taken for granted by the illocutionary agents in s.
(19c) A implicates B = use of A in a situation s suggests, everything else being equal, that B is true in s.

The definitions in (19a), (19b), and (19c) can be readily associated with "operational" tests that enable speakers to assess whether a given relation obtains or not. For example, to check whether (20a) entails (20b), you might check whether you could sincerely assert (20a) while denying (20b), viz. whether you could sincerely and felicitously utter something like (20c):

(20a) It is indeed odd that Mary is home.
(20b) Mary is home.
(20c) It is indeed odd that Mary is home, even if she in fact isn't.

To the extent that you can't really say something like (20c), you are entitled to conclude that (20a) entails (20b). It is useful, in these cases, to use contrast sets such as (21a) and (21b).

(21a) It is indeed conceivable that Mary is at home.
(21b) It is indeed conceivable that Mary is home, even if she in fact isn't.

The semantic relations in (18a), (18b), and (18c) can be viewed as intuitions of semantic relatedness speakers have about sentences of their own language, as judgments that may be elicited, and the like. By analogy with well-formedness judgments, there are some cases in which things are not so clear and we may not be sure whether, say, a certain entailment holds or not. In such a case, more complex arguments, indirect evidence of various sorts, or psycholinguistic experimentation may be called for (see, e.g., Crain and Thornton (1998) on experimental methodologies for truth-based semantic judgments). But in indefinitely many cases, simple introspection yields relatively straightforward judgments. The capacity for making such judgments is constitutive of our semantic competence. Such a competence cannot be simply a thesaurus, a store of pairs of sentences, with the relative judgment tacked on, for the number of judgments speakers can make on the fly is potentially infinite. Semantic competence must be a computational device of some sort. Such a device given an arbitrary pair of sentences <A, B> must be able to determine in principle whether A entails B, presupposes it, etc. The task of semantics is to characterize the general architecture of such a computational device. While there are many foundational controversies that permeate the field, there is a broad convergence that this is roughly the form that the problem of meaning takes within modern formal semantics.

Semantic Modeling

In the present section I will sketch how a (necessarily, much simplified) calculus of semantic relations may look. Suppose you have a lexicon of the following form:

(22a) N: John, Bill, dog, cat, table, ...
(22b) V: runs, smokes, drinks, . . .
(22c) DET: the, a, some, every, no . . . .

Think of syntax as a device that combines lexical entries by merging them in complex phrases and assigning them a syntactic analysis that can be represented by tree diagrams or labeled bracketings of the following form:

(23a) $[_{VP}$ John smokes]
(23b) $[_{DP}$ every boy]
(23c) $[_{VP}$ $[_{DP}$ every boy] smokes]

I assume, without being able to justify it, that lexical items have phrasal projections. In particular, VP is the phrasal projection of V and constitutes a clausal nucleus composed of the verb and its arguments linked in a predicative structure. Such a nucleus forms the

innermost skeleton of the sentence (I will have to ignore matters pertaining to inflection, agreement, tense, and the like). The lexical features of verbs are crucial in determining the characteristics of clausal nuclei. DP is the phrasal projection of D, and it is constituted by a determiner and a (common) noun. Clausal nuclei can be formed by merging a verb with a (proper) name or a DP, as indicated. In the spirit of the discussion in the section on **Truth and Semantic Competence**, semantics assigns recursive truth conditions to sentences in terms of the reference assigned to lexical entries. There are several ways to do this. Ultimately, the choice one makes on the exact format of interpretive rules has far-reaching consequences for our understanding of grammar. However, our choices here are only in small part dictated by our current understanding of semantics in universal grammar; for the major part, they result from considerations such as ease of exposition, keeping prerequisites at a minimum, and the like. To get started, we should assign a reference (or denotation, terms we will use interchangeably) to lexical entries. To do so, we assume we have a certain domain $D_s = \{a, b, c, \ldots\}$ at each given discourse situation s that constitutes our universe of discourse. A discourse situation can be thought of as the time at which the utterance takes place. A domain is just a set of individuals, pragmatically selected (e.g., those salient to the illocutionary agents). Interpretations are relative to an utterance situation s and the corresponding domain of discourse D_s. Reference of proper nouns, for example, is suitably chosen from the domain of discourse. Suppose, for example, that a and b are salient humans in our universe of discourse, then we might have:

(24) For any conceivably relevant utterance situation s, the name *John* denotes a in s; the name *Bill* denotes b in s . . .

It doesn't matter how a or b are characterized (via a description, an act of indication, etc.) to the extent that one successfully succeeds in linking the noun to its bearer. Also, it is useful to have a uniform category-neutral notation for semantic values; we will use for this the double bar notation $\| \ \|$; accordingly, for any expression α, $\|\alpha\|^s$ will be the semantic value of α in situation s. Thus, (24) can be abbreviated as:

(25) $\|\text{John}\|^s = a$ (where $a \in D_s$, the domain of discourse at s)

(Technically, $\| \ \|$ can be viewed as a function from expressions and situations into denotations; so sometimes we will speak of the interpretation function.) The denotation of a simple (intransitive) verb such as those in (22b) can be thought of as a function that for each (appropriate) individual in the domain discourse tells us whether that individual performs a certain action or not. Here is an example:

(26) *smokes* in a situation s denotes a function $\mathbf{smoke}_s$ that applies to animate individuals and returns truth values. If a is such an individual, then $\mathbf{smoke}_s(a)$ returns 'true' (which we represent as the number 1) if that individual performs the action of smoking in s (where smoking involves . . . .); otherwise $\mathbf{smoke}_s$ (a) returns 0 (i.e., 'false').

If a is not animate (e.g., if a is a stone and s is a 'normal' situation), then $\mathbf{smoke}_s$ (a) is not defined (lacks a value). The final part in definition (26) reflects the fact that sentences like (27a) and (27b), out of the blue, are (equally) strange: smoking normally requires its subject argument to be animate.

(27a) That stone smokes.
(27b) That stone doesn't smoke.

The deviance of sentences like (27a) and (27b) has been variously characterized as a violation of selectional restrictions or as sortal deviance. Here we are couching the relevant phenomenon in presuppositional terms (to illustrate a further application of such a concept). The fact that sentences of this sort remain deviant across negation may be taken as evidence that the verb *smoke* imposes an animacy presupposition on its arguments (see e.g., Chierchia and McConnell-Ginet (2000) for more discussion). A definition like (26) can be stated more compactly:

(28) $\|\text{smokes}\|^s = \mathbf{smoke}_s$,
where for each a in D_s, $\mathbf{smoke}_s(a)$ is defined iff a is animate in s; if defined, $\text{smoke}_s(a) = 1$ if a smokes in s (where smoking involves . . .); $\mathbf{smoke}_s$ (a) = 0, otherwise.

The definition of (or constraints on) smoking (i.e., the dots in (28)) can be elaborated further in several ways by refining our lexical analysis of the verb *smoke*. Although much progress has been made on this score, many important issues remain open (including, e.g., whether a presuppositional treatment of selectional restrictions is ultimately viable). What is important, from the point of view of compositional semantics, is the *logical type* or *semantic category* of the denotation of a verb like *smoke*. Such verbs are treated here as functions from individuals into truth values. These are called *characteristic functions*; they divide the (relevant portion of) the domain of discourse of the utterance situation in two: the things that satisfy the verb from those that don't. Characteristic functions correspond to sets (which might be called the *extension* of the function), as the following example illustrates:

(29) Let universe of discourse be {a, b, c, d}; let a, b, and c be people. Of these, let a and b smoke in s while b but not a also smokes in a different situation s'. We can represent all this as follows:

$$\textbf{smoke}_s = \begin{array}{l} a \rightarrow 1 \\ b \rightarrow 1 \\ c \rightarrow 0 \end{array} \text{ corresponding extension: } \{a,b\}$$

$$\textbf{smoke}_{s'} = \begin{array}{l} a \rightarrow 1 \\ b \rightarrow 0 \\ c \rightarrow 0 \end{array} \text{ corresponding extension: } \{a\}$$

As is evident from the example, sets and characteristic functions are structurally isomorphic (encode the same information). In what follows it will be useful on occasion to switch back and forth between these two concepts. Use of characteristic functions as a formal rendering of verb meanings is useful in giving truth conditions for simple subject predicate sentences:

(30a) A sentence of the form $[_{VP}$ N V] is true in s iff $||V||^s (||N||^s) = 1$

Example:

(30b) $[_{VP}$ Bill drinks] is true in s iff $||\text{drinks}||^s (||\text{Bill}||^s) = 1$

The truth conditions of any sentence with the syntactic structure specified in (30a) boil down to applying a characteristic function to an individual (and thereby ascertaining whether that individual belongs to the set that constitutes the extension). To find out whether Bill in fact smokes in s, we need factual information about the situation obtaining in s. To understand the sentence, we don't. We merely need to know its truth conditions, which in the case of simple subject–predicate sentences are an instruction to check the value of a characteristic function for the argument specified by the subject. The rules in (30a) and (30b) can be reformulated more compactly as in (31):

(31) $||\,[_{VP}\ N\ V\ ]\,||^s = ||V||^s (||N||^s)$

This can be viewed as the kernel of a predication rule (that tells us how subject and predicates combine semantically).

Everything so far looks like a formally explicit (and perhaps somewhat pedantic) way of sketching a denotational, information-oriented semantics, and the reader may get the feeling of not yet finding striking insights on what meaning is. In order to grasp the potential of this method, one needs to look at a little more of its computational apparatus. So let us turn now to DPs. Things here are definitely more challenging. DPs are constituents formed by a determiner plus a common noun. Common nouns can be given, at least in first approximation, the same analysis as (intransitive) verbs, i.e., the meaning of, say, *cat* can be thought of as a characteristic function that selects those entities that are cats out of the universe of discourse (or, equivalently, we can say that *cat* identifies a class/set across situations). But what about things like *no cat* or *every cat*, which are the typical constituents one finds in, e.g., subject position and the like? What does *no cat* denote? And, even worse, what do *no* or *every* or *some* denote? Our program is to assign a denotation to lexical entries and then to define in terms of it truth conditions for sentences. So we must find suitable denotations of Ds and DPs.

To address questions of this sort, we apply a heuristic that goes naturally with our general setup: whenever the denotation of an expression is not directly accessible to your intuition, look at what that expression contributes to the truth conditions of the sentences it occurs in (the epistemological primacy of sentences, again). So, consider for example:

(32) No boy smokes.

We know/assume/conjecture that *boy* and *smoke* denote characteristic functions and that sentences contribute truth values (i.e., they are true or false, as the case may be, in different situations). We may think of *no* as a function, too. As is evident from (32), such a function combines first with a characteristic function/set (corresponding to the noun); then the result combines with a second characteristic function (corresponding to the verb) to yield a truth value. Schematically, here is what we have:

(33) $\textbf{no}(\textbf{boy}_s)\ (\textbf{smoke}_s) = 1 \text{ or } 0$

Now we can look at our intuitions. When is (32) true? The answer is pretty clear. When among the boys, nobody smokes. Or, equivalently, when the class of boys (i.e., the extension of $\textbf{boy}_s$) has no member in common with the smokers (i.e., the extension of $\textbf{smoke}_s$), (32) is true. In set talk, the intersection between the boys and the smokers must be empty:

(34) $\text{no}(\textbf{boy}_s)\ (\textbf{smoke}_s) = 1 \text{ iff } \text{BOY}_s \cap \text{SMOKE}_s = \varnothing$

(where BOY_s, SMOKE_s are the extensions corresponding to $\textbf{boy}_s$, $\textbf{smoke}_s$, respectively) This is perfectly general. Replace boy/smokes with any other noun/verb. The contribution of *no* stays constant: no(N) (V) is true just in case no member of the extension of N is in V. We thus discover that *no* has a perfectly sensible (if abstract) denotation: a function that encodes a relation between sets. Our contention here is that speakers behave as if they had such a function in mind (or something similar to it) in using *no*.

The next step is to see that *all* determiners express relations among sets (characteristic functions), just like *no* does. Here are a few examples, along with some comments.

(35a) *Some*
(35a.i) Example: some boy smokes
(35a.ii) Truth conditions: **some**(**boy**$_s$) (**smoke**$_s$) = 1 iff $BOY_s \cap SMOKE_s \neq \emptyset$
(35a.iii) Comment: *some* is the contrary of *no*; *some boy smokes* is true just in case you can find someone among the boys who is also among the smokers; i.e., the intersection between the class of boys and the class of smokers must be non empty. The indefinite article *a* can be analyzed along similar lines.
(35b) *Every*
(35b.i) Example: every boy smokes
(35b.ii) Truth conditions: **every**(**boy**$_s$) (**smoke**$_s$) = 1 iff $BOY_s \subseteq SMOKE_s$
(35b.iii) Comment: *every* expresses the subset relation: *every boy smokes* is true just in case all the members of the class of boys also belongs to the class of smokers
(35c) *Most*
(35c.i) Example: Most boys smoke
(35c.ii) **most**(**boy**$_s$) (**smoke**$_s$) = 1 iff the number of member of $BOY_s \cap SMOKE_s$ is bigger than half the number of members of BOY_s.
(35c.iii) Comment: *most* involves actual counting. *Most boys smoke* is true just in case the number of boys who smoke (i.e., the intersection of the boys with the smokers) is greater than half the number of boys (i.e., more than half of the boys are smokers).
(35d) *The*
(35d.i) Example: The blond boy smokes.
(35d.ii) Truth conditions: **the** (**blond boy**$_s$) (**smoke**$_s$) is defined only if there is exactly one blond boy in s. Whenever defined, **the** (**boy**$_s$) (**smoke**$_s$) = **every** (**boy**$_s$) (**smoke**$_s$).
(35d.iii) Comment: this reflects the fact that *the blond boy smokes* is only interpretable in situations in which the universe of discourse contains just one blond boy. If there is more than one blond boy or if there is no blond boy, we wouldn't really know what to make of the sentence. So *the* is a presuppositional determiner; it presupposes the existence and uniqueness of the common noun extension. (This analysis of *the* goes back to Frege.)

In spite of the sketchiness of these remarks (that neglect important details of particular determiners), it should be evident that the present line of analysis is potentially quite effective. A class of words and phrases important and tendentially stable across many languages falls into place: determiners ultimately express natural relations between sets (the set associated with the common noun and the set associated with the verb phrase). Our denotational perspective seems to meet rather well the challenge that seemingly denotationless items pose. It is useful to see what becomes of our rule of predication (viz. (31) above). Evidently such a rule needs to be split into two (main) subcases, depending on whether the subject is a simple N (a proper name) or a complex DP. Here is an exemplification of the two cases:

(36a) Mary smokes.
(36b) No boy smokes.

In case (36a), we have semantically two pieces: an individual (whomever *Mary* denotes) and a characteristic function (**smoke**$_s$); so the latter applies to the former. In case (36b) the two pieces are: a complex function (namely **no** (**boy**$_s$)) that looks for a characteristic function to yield a truth value, and, as before, the characteristic function **smoke**$_s$; in this case the former applies to the latter. In either case, the end result is a truth value. So our predication rule becomes:

(37a) $\| [_{VP}\ N\ V\ ] \|^s = \|V\|^s (\|N\|^s)$
(37b) $\| [_{VP}\ DP\ V\ ] \|^s = \|DP\|^s (\|V\|^s)$

This suggests that the core rule of semantic composition is functional application. Consider for example an ungrammatical sentence of the form:

(38) * $[_{VP}$ boy smokes]

Such a sentence, as things stand, would be generated by our (rudimentary) syntax. However, when we try to interpret it, we find two characteristic functions of individuals, neither of which can apply to the other. Hence, the sentence is uninterpretable, which explains its ungrammaticality. There are languages like, for example, Russian or Hindi where singular common nouns without a determiner can occur in subject position:

(39a) Russian: mal'cik kurit boy smokes 'the boy smokes'_
(39b) Hindi: kamre meN cuuha ghuum rahaa hai (from Dayal 2004) room in mouse moving is 'a mouse is moving in the room'

Notice that (39a) is the verbatim translation of (38) and is grammatical in Russian. The line we are taking suggests that in such languages it must be possible to turn some covert forms of common nouns into

argumental DPs, i.e., things that can semantically combine with predicates; for example it is conceivable that in a language without articles, like Russian, the semantic functions associated with the articles can be applied covertly (as part of the interpretive procedure), so as to rescue the semantic mismatch that would otherwise ensue. This may, in turn, involve the presence of a phonologically null determiner (for alternative developments of this line of analysis, as well as details concerning the available interpretations, see, e.g., Chierchia (1998), Longobardi (2001), and Dayal (2004)).

The picture that emerges is the following. The basic mode of syntactic composition is *merge*, or some analogously simple operation that puts together two constituents (subject to parametrization pertaining to, e.g., word order, case, etc.). The basic mode of semantic composition is *apply*: constituents are compositionally analyzed as functions (of more or less complex semantic type) and arguments (individuals or other functions); so whenever we find a function and an argument of the appropriate sort, we simply apply the former to the latter. If things go wrong at any level, the derivation crashes and the result is ungrammatical. The semantic side of this process has come to be known as 'type driven interpretation,' the main idea being that the semantic categories of functions and arguments drive the interpretation process.

The present approach directly yields a computationally tractable theory of entailment and presupposition. We have defined entailment roughly as follows: a sentence S entails a sentence S' iff whenever S is true, S' is also true. The apparatus we have developed allows us to prove whether a certain entailment holds or not. Let me show, as an illustration, that (40a) entails (40b) but not vice versa.

(40a) Every scientist smokes.
(40b) Every mathematician smokes.

To show this we need to assume that if one is a mathematician, one is a scientist; i.e.,

(41) For every individual a,
(41a) if $\mathbf{mathematician}_s$ (a) = 1, then $\mathbf{scientist}_s$ (a) = 1 or, equivalently:
(41b) $\text{MATHEMATICIAN}_s \subseteq \text{SCIENTIST}_s$

Consider now the semantics of (40a), according to our analysis. It is the following:

(42) $\mathbf{every}(\mathbf{scientist}_s)\ (\ \mathbf{smoke}_s)$

In virtue of (35b), this is tantamount to

(43) $\text{SCIENTIST}_s \subseteq \text{SMOKE}_s$

This being so, every subset of the set of scientists must also be included among the smokers (by elementary set theoretic considerations). Since, in particular, mathematicians are scientists, it follows that

(44) $\text{MATHEMATICIAN}_s \subseteq \text{SMOKE}_s$

But this is just the semantics of (40b). So, if (40a) is true in s, then (40b) must also be true in s. Evidently, this reasoning goes through no matter which situation we are in. Hence, (40a) does entail (40b). On the other hand, it is easy to conceive of a situation in which (44), and hence (40b), hold, but say some economist doesn't smoke; in such a situation, (43) would fail to obtain. Hence, (40b) does not entail (40a).

A fully parallel way of reasoning can be put forth for presuppositions. We said that S presupposes S' iff S' must be taken for granted in every situation in which S is asserted, denied, etc. This can be cashed in as follows. We can say that for S to be true or false (i.e., to have a semantic value that makes it suitable for assertion or denial), S' must be known to be true in the utterance situations by the illocutionary agents, i.e., S can be true or false in s iff S' is true in s. Using this definition (known as the 'semantic' definition of presupposition), we can formally prove (though we will not do so here) that, for example, (45a) presupposes (45b):

(45a) The blond boy smokes.
(45b) There is exactly one blond boy around.

The general point of these examples is the following. Intuitions about entailment and the like are *a priori*; speakers have them just by inspecting the meaning of the relevant sentences. In the present setup, this central fact is captured as follows. Semantics can be viewed as a set of axioms that (a) determines the interpretation of lexical entries and (b) assigns truth conditions to sentences. Such apparatus yields a calculus of entailment (and other semantic relations) that reemerge as theorems of semantics. We have not formalized each single step of the derivation (relying on the readers' patience and understanding of elementary set theory); but such a formalization is, evidently, feasible. We not only thereby gain in clarity. We also obtain a device that constitutes a reasonable (and falsifiable) model of speakers' linguistic abilities. The claim is not that the specific rules we have given are actually implemented in the speakers' mind. The claim is that speakers, to the extent that they can be said to compute entailments must be endowed with computational facilities that bear a structural resemblance to the ones sketched here. This, in turn, paves the way for inspecting the architecture of our linguistic abilities

ever more closely. Without excessive optimism and in full awareness of the controversies that permeate the field, this seems to constitute a step in the right direction.

One further remark on the general picture that emerges from the sketch above cannot be avoided. Our approach to meaning is denotational: we assign a denotation to words and morphemes and (in terms of such denotations) truth conditions to sentences. This can be understood in several ways, of which I will present two much simplified extremes. We can take truth condition assignment as a way of exposing the link between language and the world, which is, arguably, the ultimate goal of semantics. Words/morphemes are actually mapped into aspects of the world (e.g., names are mapped into actual individuals); sentences are symbolic structures that code through their fine structure how things may be arranged in the world. However, it is also possible to view things somewhat differently. What really matters, it can be argued, is not the actual mapping between words and aspects of reality and between sentences and the conditions under which they, in fact, are true. What we do is give a form or recipe or potential for actual truth conditions; we merely constrain the form that truth conditions may take. What we get out of this is what really matters: a calculus of semantic relations (entailment, presupposition, etc.). Unlike what happens in, say, pure logic, such a calculus is not a normative characterization of sound reasoning; it is an empirically falsifiable characterization of semantic competence (i.e., of what speakers take to follow from what, when). Under the latter view, truth conditions (or truth condition potentials, or whatever it is that we map sentences on) are a ladder we climb on to understand the working of semantic relations, i.e., relations that concern the information content of linguistic expressions.

It is evident that we are not going to settle these issues here. As a small consolation (but also, if you wish, as evidence of the maturity of the field), I hope to have given the reader reasons to believe that progress is possible even if such foundational issues remain open.

We haven't discussed implicatures and other pragmatically driven intuitions about meaning. To understand the full scope of the present proposal, it is important to do so. This requires extending a bit what we have done so far.

The Semantics/Pragmatics Interface

In the section **Truth and Semantic Competence**, we mentioned implicatures, a broad and varied type of meaning relations. We will elaborate by looking more closely at the oscillation in the meaning of *or*. The purpose is to illustrate how generalized implicatures come about and how this bears on the view of semantics sketched in the preceeding section on **Semantic Modeling**.

The first step is to attempt a semantic analysis of *or*. To this we now turn. Imagine we extend our grammar by introducing coordination and negation along the following lines:

(46a.i) [$_{VP}$ John doesn't smoke]
(46a.ii) [$_{VP}$ NEG VP]
(46b.i) [[$_{VP}$ John smokes] and/or [$_{VP}$ Bill smokes]]
(46b.ii) [VP and/or VP]

The syntax of negation and coordination poses many thorny questions we simply cannot address here. Although for our purposes any number of assumptions concerning syntax might do, let us maintain, again without much justification, that a negative sentence like (46a.i) has the structure in (46a.ii) out of which the observed word order is derived by moving the subject left from the inner VP. Furthermore, we will assume that coordinated sentences, whether disjunctive or conjunctive, such as (46b.i), are obtained through schemas such as (46b.ii). Insofar as semantics is concerned, the introduction of negation, conjunction, disjunction, etc., poses problems similar to that of determiners. The relevant expressions are function words, and it is not obvious how to analyze them in denotational terms. This question, however, can be addressed in much the same way as we have done with the determiners: by looking at what the relevant elements contribute to the truth conditions of the sentences they occur in. For sentential operators, we can draw on a rich logical tradition. In the attempt to characterize the notion of valid inference, logicians have discussed extensively propositional connectives (like *not*, *and*, *or*), and the outcome is an analysis of such elements as truth functions or, equivalently, in terms of 'truth tables.' For example, the contribution of negation to meaning can be spelled out in terms of conditions of the following sort:

(47a) *John doesn't smoke* is true in s iff *John smoke* is false in s
(47b) $\| \text{NEG VP} \|^s = 1$ iff $\| \text{VP} \|^s = 0$
(47c)

VP	NEG VP
1	0
0	1

In (47c) we display in the form of a truth table the semantics given in (47b). Essentially, this says that in uttering a negation like (47a), the speaker intends to convey the falsity of the corresponding positive sentence. By the same token, conjunctions can be

analyzed as in (48a), (48b), and (48c), and disjunction as in (49a), (49b), and (49c):

(48a) *John smokes and Bill smokes* is true if both *John smokes* and *Bill smokes* are.

(48b) $\| [VP_1 \text{ and } VP_2] \|^s = 1$ iff $\| VP_1 \|^s = \| VP_2 \|^s = 1$

	VP_1	VP_2	$[VP_1 \text{ and } VP_2]$
(48c.i)	1	1	1
(48c.ii)	1	0	0
(48c.iii)	0	1	0
(48c.iv)	0	0	0

(49a) *John smokes or Bill smokes* is true if either *John smokes* or *Bill smokes* or both are true.

(49b) $\| [VP_1 \text{ and } VP_2] \|^s = 1$ iff either $\| VP_1 \|^s = 1$ or $\| VP_2 \|^s = 1$ or both

	VP_1	VP_2	$[VP_1 \text{ or } VP_2]$
(49c.i)	1	1	1
(49c.ii)	1	0	1
(49c.iii)	0	1	1
(49c.iv)	0	0	0

This is the way in which such connectives are analyzed in classical (Boolean) logic. Such an analysis has proven extremely fruitful for many purposes. Moreover, there is little doubt that the analysis in question is ultimately rooted in the way in which negation, etc., works in natural language; such an analysis indeed captures at least certain natural uses of the relevant words. What is unclear and much debated is whether such an analysis stands a chance as a full-fledged (or nearly so) analysis of the semantics of the corresponding English words. There are plenty of cases where this seems *prima facie* unlikely. This is so much so that many people have concluded that while Boolean operators may be distilled out of language via a process of abstraction, they actually reflect normative principles of good reasoning more than the actual semantics of the corresponding natural language constructions. Of the many ways in which this problem might illustrated, I will choose the debate on the interpretation of *or*.

The interpretation of *or* provided in (49a), (49b), and (49c) is the inclusive one: in case both disjuncts turn out to be true, the disjunction as a whole is considered true. As we saw, this seems adequate for certain uses but not for others. The exclusive *or* can be analyzed along the following lines:

(50) Exclusive *or*

	VP_1	VP_2	$[VP_1 \text{ or } VP_2]$
(50.i)	1	1	0
(50.ii)	1	0	1
(50.iii)	0	1	1
(50.iv)	0	0	0

As the readers can verify by comparing (49a), (49b), and (49c) with (50), the two interpretations of *or* differ only in case (i); if both disjuncts are true, the whole disjunction is true on the inclusive interpretation and false on the exclusive one.

So, the thesis that *or* is ambiguous can be given a precise form. There are two homophonous *or*s in English. One is interpreted as in (48a), (48b), and (48c), the other as in (50). Illocutionary agents choose among these options on pragmatic grounds. They go for the interpretation that is best suited to the context. Determining which one that is will involve knowing things like the topic of the conversation (e.g., are we talking about a single job or more than one), the purpose of the conversational exchange, the intentions of the speaker, etc.

We mentioned that Grice proposed an alternative view, however. We are now in position to spell it out more clearly. If you look closely at the two truth tables in (49a), (49b), and (49c) vs. (50), you'll notice that in all the cases in which the exclusive *or* comes out true (namely case (ii) and case (iii)), the inclusive one does, too, i.e., in our terms, [p $\text{or}_{\text{exclusive}}$ q] entails [p $\text{or}_{\text{inclusive}}$ q]. The former is, thus, stronger, more informative than the latter in the following precise sense: it rules out more cases. If you get the information that [p $\text{or}_{\text{exclusive}}$ q] holds, you know that case (ii) or case (iii) may obtain, but case (i) and case (iv) are ruled out. If you know instead that [p $\text{or}_{\text{inclusive}}$ q] obtains, you know that you might be in case (i), (ii), or (iii); only case (iv) is ruled out. Your degree of uncertainty is higher. So $\text{or}_{\text{exclusive}}$ is more restrictive; $\text{or}_{\text{inclusive}}$ is more general (more liberal we said). Things being so, suppose for a moment that *or* in English is unambiguously inclusive (i.e., its interpretation is the most general, less restrictive of the two); this does not rule out at all the possibility that we are in case (ii) or case (iii). The exclusive construal, in other words, might arise as a special case of pragmatic strengthening. It is as if we silently add to, say, (51a) something like (51b).

(51a) John or Mary will be hired.
(51b) (... but not both)

The silent addition of (51b) to (51a) might be justified through a reasoning of the following sort:

(52) The speaker said (51a); let us assume she is being cooperative and not hiding on purpose any relevant information. This entails that she has no evidence that both John and Mary have been hired, for otherwise she would have said so. Assuming, moreover, that she is well-informed about the facts, this furthermore entails that she thinks that in fact (51b) holds.

So in this view, the base interpretation (viz. (51a)) is enriched through an inferential process that draws on principles of rational conversational exchanges and on factual knowledge about the context. The relation between (51a) and (51b) can thus be analyzed as a case of implicature (cf. on this, e.g., Horn (1989), Levinson (2000), and references therein).

The debate on how the two interpretations of *or* come about is important and shows different ways in which semantics is taken to interact with broader considerations pertaining to communication. Whether the two interpretations of *or* are a matter of ambiguity or arise as an implicature, I want to point out a generalization concerning their distribution, which I think shows something important concerning how language works. I will argue that the cases in which *or* is construed preferentially inclusively are (1) predictable, and (2) determined by structure. Then, I will put forth a hypothesis as to why this is so.

We have seen that a sentence like (16a), repeated here as (57a), is interpreted as in (57b), namely exclusively:

(53a) If I got it right, either John or Mary will be hired.
(53b) If I got it right, either John or Mary but not both will be hired.

Now take the consequent (i.e., the main clause) in the conditional in (53a) and move it to the antecedent, and the interpretation tends to shift:

(54a) If either John or Mary are hired, we'll celebrate.
(54b) If John or Mary or both are hired, we'll celebrate.

So, moving a disjunction from the consequent to the antecedent seems to have a systematic effect on the interpretation of *or*. The same holds for the pair in (55a) and (55b):

(55a) Every student will either take an exam or write a paper.
(55b) Every student who either takes an exam or writes a paper will satisfy the requirements.

In (55a), *or* is within the VP, which corresponds to the second argument of *every*, according to the analysis sketched in the section **Semantic Modeling**. Its preferred interpretation is exclusive. In (55b), *every* is in a relative clause which is part of the subject NP (namely, the first argument of *every* according to the analysis in **Semantic Modeling**). Its preferred interpretation is clearly inclusive.

A further class of contexts that displays a similar effect are negation and negative verbs. Compare (56a) and (56b):

(56a) I believe that either John or Mary will be hired.
(56b) I really doubt that either John or Mary will be hired.

Sentence (56a) is likely to get the interpretation 'I believe that either John or Mary but not both will be hired.' Sentence (56b), on the other hand does not have a parallel reading. It rather means 'I really disbelieve that John and Mary stand a chance.'

The list could go on. But these examples should suffice to instill in the reader the idea that there is a systematic effect of structure on the interpretation of *or*. A doubt might linger, though, as to whether it is really in the nature of structure to have this impact. Take, for example, the pair in (55a) and (55b). Is it the position of disjunction that makes a difference? Or is it rather our knowledge of how classes normally work?

This is a legitimate question. Noveck *et al.* (2002) address it experimentally. They designed a reasoning task, in which logically naïve subjects are asked to judge whether a certain inference is sound or not. For example, subjects were asked to judge whether one can infer (57c) from (57a) and (57b):

(57a) If there is an A, then there is a B or a C.
(57b) There is an A.
therefore:
(57c) There aren't both a B and a C.

Subjects were told that this was about inferences that could be drawn (on the basis of the given premises) concerning letters written on the back of a certain blackboard. What would your answer be? The experimental subjects overwhelmingly accepted the inference in (57a) and (57b). What is interesting is that in terms of classical Boolean logic (which takes *or* to be inclusive) this inference is invalid. It is only valid if *or* in (57a) is interpreted exclusively. At the same time, subjects rejected inferences of the following form:

(58a) If there is an A, then there is a B and a C.
(58b) There is an A.
therefore:
(58c) There is a B or a C.

Again, this seems to make sense only if *or* in (58c) is interpreted exclusively. Things change dramatically if *or* is embedded in the antecedent of a conditional:

(59a) If there is an A or a B, then there is a C.
(59b) There is an A; there is also a B.
therefore:
(59c) There is a C.

Subjects overwhelmingly accepted this inference as valid. But this is only possible if *or* in (59a) is

construed inclusively. Our raw intuition thus finds experimental confirmation, one that passes all due controls (the inferences were mixed with others containing other connectives and quantifiers, so that subjects were not conditioned to devise an answering strategy, and the order of presentation was duly varied, etc.). What is interesting is that these experiments only involved meaningless letters A, B, C . . . so scripts, contextual clues, knowledge of the world can hardly be imputed any role in the outcome. If there is a systematic effect on the interpretation of *or*, this must be due to the meaning of conditionals, of disjunction, and to the positioning of the latter. Nothing else is at play.

The reader may wonder how one manages to find out which structures affect the interpretation of *or*. The answer is that such structures were familiar from another phenomenon: the licensing of Negative Polarity Items (NPIs). NPIs are lexical items like *any* or *ever* that seem to require the presence of a negative element:

(60a) * There is any cake left
(60b) There isn't any cake left.

NPIs are acceptable in the contexts that favor the inclusive interpretation of *or* over the exclusive one:

(61a) * If we are in luck, there are any cookies left
(61b) If there are any cookies left, we are in luck.

(62a) * Everyone had any cookies left
(62b) Everyone who had any cookies left shared them.

This correlation is striking, for the two phenomena (the distribution of *any* and of inclusive vs. exclusive *or*) seem to have little in common.

The next question is whether the relevant contexts have some common property. The answer seems to be positive and, surprisingly, points in the direction of a rather abstract, entailment-based property. Positive contexts typically license inferences that go from sets to supersets. For example, (63a) entails (63b) and not vice versa.

(63a) There are Marlboros.
(63b) There are cigarettes.

The set of cigarettes is a superset of the set of Marlboros; so the entailment goes from a set to its supersets. Negation reverses this pattern: (64b) entails (64a) and not vice versa:

(64a) There aren't any Marlboros.
(64b) There aren't any cigarettes.

Now the VP portion of a sentence with *every* (i.e., its second argument) patterns with (63a) and (63b):

(65a) Everyone had Marlboros.
(65b) Everyone had cigarettes.

Sentence (65a) entails sentence (65b) and not vice versa. So does the consequent of a conditional

(66a) If you open the drawer, you'll find Marlboros.
(66b) If you open the drawer, you'll find cigarettes.

But the NP argument of *every* (its first argument) inverts this pattern just like negation, as we saw in the **Semantic Modeling** section:

(67a) Everyone who had Marlboros shared them.
(67b) Everyone who had cigarettes shared them.

Here it is (67b) that entails (67a) and not vice versa. The same applies to the antecedent of conditionals:

(68a) If you smoke Marlboros, you'll be fined.
(68b) If you smoke cigarettes, you'll be fined.

Sentence (68b) entails (68a); on the other hand (68a) could be true without (68b) necessarily being true (in a town in which Marlboros but no other brand is banned).

In conclusion, the contexts that favor the inclusive interpretation of *or* share a semantic property that has to do with entailment patterns: they all license entailments from sets to their subsets. Such a property has come to be seen as the property of being *downward entailing* (where *down* refers to the directionality of the entailment from sets to smaller ones). If this characterization is correct, this means that speakers to the extent that they interpret *or* as shown, must differentiate such contexts, and hence must be able to compute the entailments associated with the relevant structure.

The next question is why *or* tends to be interpreted inclusively in downward entailing structures. I will only hint at what strikes me as a highly plausible answer. As we saw above, in plain unembedded contexts, exclusive *or* is stronger (i.e., asymmetrically entails) than inclusive *or*. The set of cases in which exclusive *or* is true is a subset of the set of cases in which the inclusive one is true. We evidently prefer, everything else being equal, to go for the strongest of two available interpretations. Now, negation and, in fact, all downward entailing structures, as we just saw, reverse this pattern. Under negation, first becomes last; i.e., strongest becomes weakest. In the case of disjunction, the negation of inclusive *or* is stronger (i.e., entails) the negation of exclusive *or*. I'll leave it to the readers to persuade themselves that this is so. Now why is this observation relevant? Suppose we go for the strongest of two alternatives (i.e., we maximize informativeness, everything else being equal); for disjunction, in downward-entailing

contexts inclusive *or* is the strongest interpretation; in nondownward-entailing contexts exclusive *or* is the strongest. This explains the observed behavior in terms of a rather simple principle that optimizes information content on the basis of the available expressive resources.

So pragmatic strengthening (via a generalized implicature) correlates harmoniously with the entailment properties of various elements.

Conclusions

We have sketched a view of semantic competence as the implicit knowledge a speaker has of how the information content of various expressions is related. We have proposed to classify the hosts of semantic relations in three major families: entailment-based, presupposition-based, and implicature-based. Given two sentences, speakers can judge whether they entail each other or not, whether they presuppose each other or not, and so on; and they can do so with finite cognitive resources. We have sketched a denotational semantics that accounts for such a competence (i.e., provides a model for it). Our semantics takes the form of a calculus in which entailments, presuppositions, and even (certain) implicatures re-emerge as theorems. Such a model is formal in the sense of being explicit (building on the tradition of logic and model theory). It is, however, also substantive, in that it models a human cognitive capacity (i.e., the ability to semantically relate sentences to each other). We have seen two simple applications of this approach, to the analysis of determiners and connectives. We have also discussed a case of pragmatic enrichment. What we found is that the interpretation of *or* as exclusive or inclusive follows a pattern sensitive to downward entailingness (much like what happens with negative polarity items). If this is so, then entailment patterns are not simply an invention of logicians or linguists. They must be constitutive, in an unconscious form, of the spontaneous knowledge that endows speakers with their linguistic abilities.

often contradicting the theory under consideration, so that the cycle can start again. Progress in science is the incorporation of more and more data in the explanatory scope of the theory. This model is still adopted, usually implicitly, by many researchers working in empirical science.

Logically, the empirical cycle is not sufficiently explicit to guide scientific research. At every stage, too many alternative possibilities would have to be considered. In the transition from generalizations to theories, for instance, a sufficiently imaginative researcher could come up with more theories than they could test in their lifetime. In scientific practice, however, such problems do not arise. In the perception of most researchers, it is difficult enough to come up with a single theory that fits the data. The discrepancy between the logical plethora of theories and their scarcity in scientific practice can be explained by assuming a research program. A research program is the set of assumptions guiding the researcher toward sensible decisions at any step in the empirical cycle. These assumptions need not be conscious to the researcher and are often not formulated explicitly. In the same way as a good chess player does not see all logical possible moves but only the sensible ones, a scientist working in a research program automatically constrains the possible theories to be considered.

Chomskyan linguistics is a research program in linguistics. As such, it should be distinguished from Chomsky's linguistic theory. While both were conceived by Noam Chomsky in the late 1950s, their aims and later development are strikingly different. Chomsky's linguistic theory went through a number of stages in its development, including standard theory (ST) in the 1960s, government and binding theory in the 1980s, and the minimalist program in the 1990s. In each of these stages, tree-structure representations of sentences played a role, although the constraints on the production and manipulation of these tree structures varied. Chomskyan linguistics, by contrast, remained stable during this period. It does not refer to tree structures but specifies what a linguistic theory should explain and how such a theory should be evaluated.

Chomskyan linguistics defines the object of study as the knowledge of language a speaker has. This knowledge is called the linguistic competence or internalized language (I-language). It is not open to conscious, direct introspection, but a wide range of its manifestations can be observed and used as data for the study of language.

Competence is opposed to performance. Performance includes various types of language use; for instance, a collection of utterances, a corpus of texts, a set of grammaticality judgments, and a set of results of psycholinguistic experiments. They can be used as data in linguistic research, but in every case the relationship they have to competence should be kept in mind in their use. Naturalistic data (utterances, texts) reflect the interaction of competence with a number of other factors. Examples of such factors are knowledge of the situation in which the utterance was made, intention on behalf of the speaker, memory limitations, and degree of fatigue. Because the role of many of these factors is poorly understood, it is often difficult to use naturalistic data as evidence for the nature of competence. Experimental data also reflect competence in interaction with other factors, but in setting up the experiment, an attempt is made to control the non-competence factors. The most frequently used type of experiment is the grammaticality judgment. There is no principled reason for treating it in a special way, but because grammaticality judgments are both highly informative and easy to obtain, they have always been widely used in Chomskyan linguistics.

A grammar is a theory about the competence of an individual speaker. It describes the competence as the system underlying the observed data. As such, the grammar explains the data. The term grammar is sometimes also used to refer to competence, but this use is potentially confusing. In early stages of Chomskyan linguistics, including Standard Theory as outlined by Chomsky (1965), grammars were described in terms of rewrite rules and transformations. At this stage of the theory, rewrite rules of the type S → NP VP generated tree structures and transformations that operated on these tree structures to account for phenomena such as subject-verb agreement, passive constructions, and question formation.

The research program as described so far encounters a serious epistemological problem. If we assume a set of grammaticality judgments as our data there are infinitely many grammars (sets of rewrite rules and transformations) consistent with our data. This is a result obtained in mathematical linguistics, the theory of formal grammars. Because the aim of linguistics is to identify the grammar describing the actual competence, we need a method to distinguish this grammar from the other ones compatible with our data. Adding more data of the same type will exclude some grammars but not reduce the problem in a principled way. At any point in time, our set of data will be finite, and for any finite set of data there are indefinitely many different grammars.

As a solution to this problem, Chomskyan linguistics adopts a cross-linguistic perspective, focusing on language acquisition. In other theoretical frameworks, different languages have been compared to

reconstruct a common parent language (historical-comparative linguistics) or to find universals (typology). In Chomskyan linguistics it is assumed that certain genetically determined properties of the human mind are necessary for language acquisition. These properties are therefore reflected in one way or another in any language. By comparing different languages, linguists working in the Chomskyan framework try to find evidence of properties of the language faculty that make the acquisition of these languages possible. These properties have little in common with superficial inductive generalizations. Biologically, they are supposed to be encoded genetically in the same way as, for instance, the property that the human hand has four fingers and an opposed thumb, but they are more difficult to detect because individual languages may reflect them in different ways.

Various indications make the choice of language acquisition as the source of universals plausible. Acquisition of a language is necessary for its existence. Data from child language acquisition show that for many features of syntax, the child does not learn by repetition and resists correction. Moreover, the discrepancy between competence and performance leads to many ungrammatical and incomplete sentences in the input that children receive. The resulting I-language acquired by the child, however, is much more similar to the competence of the people in his or her environment than is a grammar that allows the sentences in the performance the child receives as input. While such considerations make a language faculty as a genetic component of the human mind plausible, conclusive empirical evidence for or against such an assumption is hard to imagine and probably impossible in principle.

In the research program of Chomskyan linguistics, the language faculty is described by a universal grammar (UG). Sometimes the language faculty is also called the language acquisition device or UG, but these names are less appropriate, because the former conflates the knowledge incorporated in the language faculty with its use and the latter conflates it with its description. The interaction of UG and grammars of individual I-languages is an essential factor in the epistemological validity of the Chomskyan research program. Since the purpose is to describe on the one hand all I-languages and on the other the language faculty that makes their acquisition possible, a proper balance has to be struck between what is genetically determined and what is acquired. If UG is too restrictive, it will not be possible to come up with grammars for all I-languages. If UG is not restrictive enough, it will not be possible to explain the learnability of the I-languages.

Figure 1 The research program of Chomskyan linguistics.

The interaction of the main components of Chomskyan linguistics can be represented as shown in Figure 1. Language is studied at the universal level (1), at the individual level (2), and at the level of data (3). These levels are represented as the three numbered boxes. On the left we find the real-world entities at each level: the language faculty, the individual competence, and the performance data. On the right we find the constructs of linguistics: UG, individual grammars, and observations about performance. At each level, the linguist's construct describes the real-world entity. In interpreting the relationships between the different levels, it should be kept in mind that there are many instances of the lower level corresponding to a single instance of the higher level. For example, by describing an I-language, a grammar can explain (aspects of) a large set of performance data. Conversely, these data can be used as a test for the grammar. At the higher level, UG describes the language faculty and explains thereby (aspects of) a large set of I-languages. Again, conversely, I-languages can be used as a test for UG, because UG has to allow for a descriptively adequate grammar that is in addition learnable.

While Chomsky (1965) recognized the epistemological need for UG, he also observed that ST did not incorporate the mechanisms for formulating it. By progressive generalization and cross-linguistic

comparison, a model of the language faculty emerged, which was formulated as the Government and Binding Theory (GB theory) by Chomsky (1981). In this model, UG consisted of a number of principles, which were universal. Differences between I-languages were accounted for by including parameters in the principles. A parameter specified a number of options, typically two. In language acquisition, parameters were set by selecting one of these options. The grammar of an I-language was thus determined by the parameter settings selected. The Minimalist Program (MP) outlined by Chomsky (1995) changed many of the theoretical assumptions of GB theory but continued to adhere to the principles and parameters model. An example of a difference between GB theory and the MP is the way movement was constrained. In GB theory, the individual transformation rules of ST were replaced by a single, general rule move α. This meant that anything could move anywhere unless a constraint prohibited it. In the MP, the perspective was reversed: every movement had to be motivated.

A noteworthy consequence of Chomskyan linguistics is that language can be studied at the level of individual I-languages or of the universal language faculty, but not at the level of major languages or dialects. There is no sense of **language** in Chomskyan linguistics, such that, for instance, David Beckham and Paul McCartney share the same language. Since they have different minds, they cannot share a mental component. The similarity of their I-languages, which by no means amounts to identity, can be explained as a consequence of the limited choice permitted by parameter settings, combined with a large overlap in vocabulary.

Other Mentalist Approaches

Adoption of a formalist approach to linguistics and acceptance that language is a knowledge component in the mind of the speaker by no means implies adherence to the research program of Chomskyan linguistics. There are many different ways of elaborating these two basic assumptions into a research program. Although the research program of Chomskyan linguistics has been debated more intensively and developed in more detail, this does not mean that the others are less valid in any sense. In this section, two approaches will be presented that have been developed over the past decades and continue to attract a significant group of researchers: Lexical-Functional Grammar (LFG) and Head-driven Phrase Structure Grammar (HPSG).

Lexical-functional grammar emerged in the late 1970s as a reaction against certain aspects of Chomskyan linguistics. However, the main focus of debate at the time was not the research program of Chomskyan linguistics, as described in the previous section, but the interpretation of a number of individual theoretical results. An example of a prominent issue was the so-called psychological reality of grammars for individual languages. In any stage of Chomskyan linguistics, a sentence is represented as a tree structure generated by rewrite rules and subsequently affected by transformations that move elements of the tree to other positions. The principles and parameters of GB theory are constraints on rewrite rules and movement. Some researchers argued that if such a grammar is a psychologically real description of the speaker's competence, a sentence that requires more movement operations or more complex ones should take longer to process than one with fewer or simpler movement operations. They devised psycholinguistic tests to evaluate this hypothesis and found that processing times were not affected in the expected way. Cognitive complexity could not be related to the complexity of syntactic derivations in a transparent way. This stimulated the development of grammar formalisms in which the role of transformations was reduced or eliminated. Lexical-functional grammar is one of the most successful of them.

As the contributions to Bresnan (1982) indicated, LFG was devised mainly by Joan Bresnan. Instead of tree structures and transformations, LFG has a tree structure and a functional structure for each sentence. The functional structure represents grammatical functions, such as subject and predicate, in a feature structure. The tree structure and the functional structure are linked by a unification-based procedure. In this way, transformations are no longer required, so the problem they pose for the psychological reality of grammars no longer arises.

At first sight, the research program of LFG was not fundamentally different from that of Chomskyan linguistics. Superficially, the main difference seems to be the nature of the grammar formalisms. A grammar in LFG also intends to describe the competence of a speaker. When we consider the universal level, however, a more principled difference can be observed. Lexical-functional grammar assumes that the formal mapping procedure between the tree structure and the functional structure is universal. This assumption constrains the formulation of grammars in a way parallel to the function of UG in Chomskyan linguistics. This means that the language faculty in LFG is interpreted not as the knowledge needed for language acquisition but as a mechanism for language processing. Therefore, the research program of LFG can also be represented as in Figure 1, but rather than UG, a

universal mechanism for processing language, i.e., mapping between form and meaning, describes the language faculty.

Another influential framework is HPSG, which emerged in the 1980s. Originally, as represented in Pollard and Sag (1987), it was strongly influenced by logical approaches to syntax (generalized phrase structure grammar; see the following section) and semantics (situation semantics). In more recent representations of the framework, Pollard and Sag (1994) and Sag and Wasow (1999) adopted a mentalist position. However, work in HPSG is more concerned with developing grammars than with discussing their status. In HPSG formalism, tree structures have been replaced entirely by feature structures. Rather than different levels of representation that are related to each other by transformations or other operations, HPSG adopts a single level. All information about what is called a sign (lexical item, phrase, sentence, etc.) is combined into a single structure. This includes phonology, syntax, semantics, and pragmatics. Relationships between components of the structure are indicated by co-indexation. This applies to both, for instance, a pronoun and its syntactic antecedent and to syntactic, semantic, and pragmatic representations of the same item. The grammar formalism in HPSG seems to be understood as a universal mechanism with language-specific parameters for building up feature structures, which suggests a research program similar to the one for LFG. The HPSG literature is in general more interested in describing individual languages than in the nature and status of universals.

Purely Formalist Approaches

Formalist approaches to grammar are often labeled as generative grammar. The term 'generative' stems from the theory of formal languages. A formal grammar is a set of rewrite rules that generates a set of sentences. The set of sentences is called a language.

In early Chomskyan linguistics, the mechanism of rewrite rules played an important role as a theoretical device. The role of the formulation of individual rewrite rules has declined in the transition to the principles and parameters model in GB theory. The conception of a language as a set of sentences goes counter to the definition of the research topic in any stage of Chomskyan linguistics. Chomsky (1986) called it an E-language (*E* for externalized), as opposed to the I-language he wanted to study.

Other linguists and philosophers pursued the idea that natural language should be studied as a set of grammatical sentences. Quine (1972) summarized the epistemological implications of this assumption. In his view, a language like English is ultimately a set of grammatical sentences. Although this set is infinite, it can still be determined for each sentence whether it is grammatical or not. For any set of sentences, there are infinitely many possible grammars. Rather than finding the correct one among them, this approach considers all of them as equally valid. It is not the knowledge of individual people that is interesting but only the language as an abstract object. English is an abstract object, of which individual speakers have imperfect knowledge, encoded in potentially quite different, more or less imperfect grammars. This position was elaborated by Katz and Postal (1991).

In the domain of semantics, this view of language has a long tradition in the philosophical study of truth and reference. In formal logic, models were developed for calculating whether a particular logical formula is true or false, given a specific assignment of truth values to primitive statements. It was Richard Montague who extended the use of these mechanisms to complex phenomena in natural language, such as quantification. Compared to Chomskyan linguistics, Montague grammar reversed the relative importance of syntax and semantics. Whereas in Chomskyan linguistics, syntax is the central area of linguistics, Montague found syntax not interesting by itself but only as a contribution to calculating the semantics of sentences. He used categorial grammar instead of rewrite rules to represent syntax. In this formalism, constituents are characterized in terms of their relationship to referring expressions and truth values. His model-theoretic semantics was meant to characterize formally the set of possible worlds corresponding to the truth of a sentence. After Montague's death, a large number of followers continued to pursue this idea.

In the domain of syntax, the progressive formulation of principles generalizing over individual rules in Chomskyan linguistics gave rise to the objection that the grammars were no longer generative because they were not formalized in enough detail to determine whether a particular sentence would be generated or not. Many researchers who had been attracted by Chomsky's (1965) ST because of its formality did not accept this development. The introduction of these principles was motivated at least in part by the problems caused by the excessive mathematical power of transformations. Therefore, Gerald Gazdar developed a formalism that approached this problem in an alternative way and dispensed with transformations altogether. In Generalized Phrase Structure Grammar (GPSG), even long-distance dependencies are expressed in terms of a purely 'context-free grammar' (CFG). A CFG consists only of rewrite rules of

the type A → α, where A stands for a single symbol and α for a string of symbols. An example of a long-distance dependency is found in the following: *Who did John think Mary loves?* Here, *who* is interpreted as the object of *loves*. In Chomskyan linguistics, the usual way of expressing this is to say that *who* originates to the right of *loves* but is moved to the start of the sentence by a sequence of transformations. Gazdar demonstrated that a CFG can account for this as well as for many other relationships traditionally described with transformations. To achieve this, he decomposed syntactic categories into feature structures and formulated so-called meta-rules. A meta-rule is a rule that takes a CFG rule as input and produces another CFG rule. Meta-rules have access to individual features inside the syntactic categories.

One of the main advantages of CFGs is their easy implementation on a computer. However, Barton *et al.* (1987) demonstrated that the system of meta-rules adopted in GPSG made grammars computationally intractable. Although GPSG has lost much of its attraction and is no longer pursued as a major grammar formalism, it contributed significantly to the theory of feature structures and was at the basis of the HPSG formalism.

Formalist approaches in the narrow sense do not have a research program parallel to the ones discussed in earlier sections of this article. They do not investigate language as an empirical entity, represented in the speaker's mind but only as an abstract object. As a consequence, their research is not guided by the empirical cycle. It is more similar to formal logic or mathematics, in which theorems are derived from axioms. The axioms correspond to the grammar and the theorems to the sentences. Contrary to common practice in logic and mathematics, formal linguistics starts with a set of theorems (grammatical sentences) and non-theorems (ungrammatical sentences) and searches for a set of axioms that generates all theorems and none of the non-theorems.

Aspects of Language Use

In all formalist approaches to linguistics, the theory of the language system is intended to be part of a general, empirical account of language-related phenomena. The hypothesis that language can be described as an autonomous system, whether realized as a component of the mind/brain or as an abstract system, implies that the interaction between this system and other factors can be invoked to account for phenomena related to language use.

The use of language in communication is one of the most prominent phenomena that have to be covered in this context. Yet it should be emphasized that language and communication are independent. This contrasts with the view adopted in functionalist approaches, where communication is invoked to explain language. In formalist approaches, language is not considered as a tool for communication (although it can be used for communication) and communication is not seen as dependent on language (although it often involves language). By recognizing this mutual independence, relevance theory, as developed by Sperber and Wilson (1986), is compatible with formalist approaches to the description of language. In HPSG, the information pertaining to language use can be encoded directly in the feature structures representing signs. In Chomskyan linguistics, it has been suggested that there is a mental component of pragmatic competence interacting with grammatical competence. Kasher (1991) elaborated this idea.

Since the 1980s, a number of other phenomena based on language use have gained a prominent position on the research agenda of Chomskyan linguistics. They include first and second language acquisition and language change. The reason for their prominence is that they can be used as a source of data about the principles and parameters involved in language.

Whereas the logical problem of language acquisition is at the basis of the language faculty hypothesis discussed in the section on Chomskyan linguistics, the practical problem of first language acquisition is analyzed in the principles and parameters model as the process of parameter setting by the child on the basis of performance data provided by people in the child's environment. The main question here is how the language faculty interacts with general cognitive development. Wexler (1999) advocated the hypothesis that the language faculty matures in the process of language acquisition. Lust (1999) proposed instead that the language faculty remains stable and that the first language competence is a distinct component from the language faculty.

Second language acquisition leads to a state of competence that is usually less than the one achieved for the first language. It is often called interlanguage. In Chomskyan linguistics, an interlanguage is an I-language. The question is what roles are played by such factors as the learner's cognitive development, the type of access to the language faculty, and the first language competence in the emergence of interlanguage competence. Gregg (1996) gave an overview of some of the main positions.

Language change is the historical development of languages such as English. In Chomskyan linguistics, English is considered an epiphenomenon. Its change means that different generations of speakers have systematic differences in language competence. Lightfoot (1999) presented a model in which it is assumed that parameter settings determining a speaker's grammar do not change in their lifetime but their use of the grammar does. The use of certain constructions may drop below a threshold necessary for a new generation of speakers to set the parameters in the same way as their parents. When this happens, the language is perceived as having changed.

In this section, various fields have been touched upon that crucially involve language use. The role that these fields play in approaches to linguistics that assume an autonomous system of language demonstrates that this assumption does not prevent the study of language use. Instead, it guides this study in a fruitful and constructive direction. The principles and parameters model adopted in Chomskyan linguistics stimulates this type of research in particular, because it provides external evidence about the nature of principles and parameters.

primary subgroup of Austronesian. There is a 10th group, Malayo-Polynesian, which includes all the other 1100 or so Austronesian languages spoken outside Taiwan (Yami of Orchid Island, politically part of Taiwan, is a Malayo-Polynesian language). If one accepts Blust's hypothesis, then the Formosan languages of Taiwan comprise 9 out of the 10 subgroups of Austronesian.

Blust's grouping is questionable in the view of some scholars because phonological innovations may diffuse across linguistic boundaries. A more conventional grouping is shown in Tsuchida's (1983) map. It has just three groups: Atayalic, Northwest Formosan (comprising Taokas-Babuza, Saisiyat, and Pazeh) and Southern Formosan, which includes three smaller groups, Tsouic, Rukai, and Paiwanic (comprising Amis, Bunun, Puyuma, and Paiwan). Other Formosan languages are ungrouped. This grouping and variations on it are open to the criticism that they are based on shared similarities, not on shared innovations, and are therefore not subgroups in the standard sense of the linguistic comparative method.

It is possible that there will never be a full agreed subgrouping of Formosan languages. Speakers of Proto-Austronesian probably arrived in Taiwan from mainland Asia some 5000 years ago, and it is a reasonable inference that as their descendants populated Taiwan the language diversified first into a dialect network, then into individual languages. Contact between speakers of different languages would have continued, with concomitant mutual influence (and different patterns of contact at different times), leaving complex patterns of shared phonological features, lexicon, and grammatical constructions, the historical significance of which it is difficult to disentangle. Perhaps half the Formosan languages have disappeared since the early 17th century, hampering the task of historical reconstruction yet further.

There is, however, agreement among a number of scholars that Taiwan is the Austronesian 'homeland.' The reason why all Austronesian languages outside Taiwan belong to a single subgroup is that they are descended from a single language whose speakers appear, on current archaeological evidence, to have migrated southward from Taiwan to the Philippines about 4000 years ago.

The History of Formosan Language Studies

The first outsiders to study Formosan languages were probably Dutch missionaries in the early 17th century. Our knowledge of the extinct Siraya language, for example, comes from a New Testament translation and other documents printed by the Dutch (Adelaar, 2004). There is evidence that some Dutch observers recognized similarities between Formosan and Malay vocabulary, but the first explicit statement that Formosan languages belong to what we now call the Austronesian family is found in Klaproth (1824). The first modern examination of the historical position of the Formosan languages was Dyen (1963), and Dahl (1973) was the first major work on the reconstruction of Proto-Austronesian to incorporate Formosan material.

Japanese linguists and anthropologists made quite extensive studies of Formosan speakers and their languages, resulting in the publication of Ogawa and Asai (1935). The first 20th-century description of a Formosan language to appear in a Western language was Asai's (1934) account of Seediq. The first description to be published after World War II was Tung (1964) on Tsou and two articles by Egerod (1965, 1966) that provided a sketch of Atayal grammar. This trickle has grown to a flow since the early 1970s, with grammars, dictionaries, text collections, as well as journal articles and Taiwanese M.A. theses, which mostly deal with one aspect of one language. Several single-language dialect comparisons were published by Paul Li and his colleagues at the Academia Sinica in the 1970s and 1980s. However, considerations of space allow only a restricted literature survey, and (with a few exceptions) only published book-length works in Western languages dealing with living Formosan languages are mentioned.

Languages are discussed in a roughly north-to-south order. The Atayalic languages are among the best described Formosan languages. As well as Egerod's work, there are short grammars of two Atayal dialects (Huang, 1992, 1995) as well as an important article on verbal morphemes (Huang, 2000). Egerod (1999) provided a substantial dictionary. Asai (1934), Holmer (1996), and Tsukida (2004) each sketch the grammars of Seediq dialects.

There are as yet no readily accessible descriptions of Saisiyat or Kavalan (but see Chang, 2000). However, Li and Tsuchida (2001) and Blust (2003) have provided thorough documentation of two languages on the verge of extinction, Pazeh and Thao. Ironically, for Amis, the Formosan language with the most speakers, there is only a partial description in a rather opaque framework (Chen, 1987). There is also a dictionary by Fey (1986). Bunun, another language with quite a large population of speakers, has received little attention since Jeng (1977).

Tsuchida (1976) provided sketches of the three Tsouic languages in the course of reconstructing Proto-Tsouic. Tsou had already been described by Tung (1964) and it has received continuing attention

(see Zeitoun, 2004), but Kanakanavu and Saaroa are in danger of becoming extinct before being further described. Rukai was documented and described by Li (1973) and its dialects have been described in articles by Zeitoun (1997).

The grammar of one Puyuma dialect is described in Japanese with English glosses by Tsuchida (1980). Cauquelin (1991a, 1991b) provides a grammar sketch and a dictionary of another dialect. Paiwan competes with Atayal for the privilege of being the best described Formosan language, with two dictionaries (Ferrell, 1982; Egli, 2002), a grammar (Egli, 1990), and a collection of texts, some of them from Japanese work in the 1930s (Early and Whitehorn, 2003).

The documentation of Formosan languages is thus patchy, with significant gaps when it comes to comprehensive language descriptions and dictionaries. Recently a series of short reference grammars in Chinese, of which Chang's work (2000) is an example, has been published.

The Structure of Formosan Languages

The Paiwan examples below are typical of those used to illustrate the basic structural features of Formosan clauses. Each NP is marked, either by a pronominal form or by a morpheme preceding the NP, as absolutive, genitive, or oblique (a locative marker *i* precedes or replaces the oblique in certain contexts). The verb has an affix that assigns one of four broad semantic roles to the absolutive (the 'nominative' in Formosanist parlance). This affixation is the most salient feature of Formosan languages, also shared by many Philippine languages.

q<m>ałup = aken tua vavuy i (tua) gadu
<ACTOR>hunt = ABS:1SG OBL pig LOC (OBL) mountain
'We hunt boar on the mountain.'

qałup-en nua tsautsau a vavuy i (tua) gadu tua vuluq
hunt-PATIENT GEN man ABS pig LOC (OBL) mountain OBL spear
'The man hunts the pigs in the mountains with a spear.'

ku = qałup-an a gadu tua vavuy
GEN:1SG = hunt-LOCATION ABS mountain OBL pig
'We hunt boar on the mountain.'

ku = si-qałup a vuluq tua vavuy
GEN:1SG = INSTRUMENT-hunt ABS spear OBL pig
'We hunt boar with a spear.'

Morphologically this is an absolutive–ergative system. The verb with ACTOR marking is intransitive, i.e., anti-passive-like, while the verb in each other example is transitive, with two core arguments: a genitive-marked actor ('genitive' because it may also serve as possessor within a NP) and an absolutive-marked NP whose role is indicated by the verbal affix.

By Formosanist convention, the verbal affix is a 'focus affix.' It would be more appropriate, however, to call it an applicative. Applicatives usually occur in nominative-accusative languages, where they change the role of the object. Here, with absolutive–ergative alignment, they change the role of the absolutive. The conventional idea that the 'focus affix' marks the semantic role of the absolutive is also suspect. On other verbs, the affixes marked as LOCATION and INSTRUMENT mark other semantic roles. The common feature is that they progressively reduce the affectedness of the absolutive NP.

Analyzing the non-actor markers as applicatives allows us to regard the construction in which they occur as a single, 'Undergoer' voice, in opposition to the anti-passive or Actor voice. All Formosan languages except Rukai have a voice system similar to Paiwan (with some morphological differences), but its use in discourse varies from language to language (Huang, 2002). In Tsou and Puyuma, the Undergoer voice is the default in narrative discourse, and the oblique-marked Undergoer in an Actor-voice independent clause is always indefinite and often nonspecific. In Paiwan and Seediq, the indefiniteness rule does not apply, and the Actor Voice behaves as an alternative default. How the speaker selects voice is not well understood.

Formulaic Language

A Wray, Cardiff University, Cardiff, Wales, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

> "a vast proportion of verbal behavior … consists of recurrent patterns, of linguistic routines" (Hymes, 1962/1968: 126).

> "our language does not expect us to build everything starting with lumber, nails, and blueprint, but provides us with an incredibly large number of prefabs" (Bolinger, 1976: 1).

Formulaic Language and Novel Language

It is universally recognized by linguists that human language is unique in its expressive potential because it enables us to produce and comprehend utterances that we have never encountered before. Most research into linguistic form has therefore tended to focus on the mechanisms by which that flexibility operates. However, evidence from psycho- and sociolinguistics, and in recent years also from corpus linguistics, indicates that there is a mismatch between the potential that human language has for novelty and the much smaller set of patterns that are actually found in our

everyday linguistic behavior. As Pawley and Syder (1983) point out, there are things that the theoretical models indicate we **can** do, but which don't seem to be done as often as they might be.

Of course, it is no surprise that languages make possible the expression of ideas that no one has ever yet needed to express. The cutting edge of human creativity is the capacity to capture a new idea and convey it to others, and unless language can facilitate that, cultural, technological and philosophical development will be greatly hampered. What is less clear is why messages that **are** often needed should also eschew the full creative potential of language. For although language makes it possible for us to express an idea in many different ways, native speakers of any given language know that there are certain preferred formulations of it. Pawley & Syder (1983) point out, for instance, that in English we say that the time is 'six forty' or 'twenty to (or before) seven,' not 'a third to (or before) seven' or 'seven minus twenty.' This is a matter of convention, not any grammatical or semantic restriction, and languages vary in their practices. In French, 'six forty' is expressed as *sept heures moins vingt* ('seven o'clock minus twenty'), while in German, *halb sieben* ('half seven') means 'half past six,' that is, half an hour before seven.

A Preliminary Definition of Formulaic Language

As with many complex phenomena, a complete definition of formulaic language is difficult to capture until a great deal is understood about it. A fuller exploration of the definition and identification of formulaic language is provided later. For now, it will suffice to say that, for most researchers, the term 'formulaic language' refers to two or more words which may or may not be adjacent and which have a particular mutual affinity that gives them a joint grammatical, semantic, pragmatic, or textual effect greater than the sum of the parts. For instance, the word string *in order to* conveys a relationship between two actions without it being clear how the three constituent words contribute to expressing that relationship. The word string *get away with you* means 'don't be ridiculous,' which is not a literal interpretation of the words. The word string *happy birthday* is a strongly favored routine for expressing good wishes, even though, by analogy with Christmas greetings, *merry birthday* ought also to be possible.

Even these few examples already highlight a number of issues that must be continually addressed when researching formulaic language. Firstly, it is clear to even a casual observer that most, if not all, formulaic word strings derive from novel constructions. This raises the question of how we are to decide precisely when a configuration should be considered formulaic rather than novel. Is *have a nice day* a formula or not? It certainly seems to have pragmatic connotations over and above its composite parts, yet if someone were to create, as novel, a grammatical sentence to wish someone a pleasant time from now until nightfall, it could well come out in precisely these words. A second, related issue is how much linguistic knowledge we should attribute to users. In the expression *if I were you*, the verb form is a subjunctive. Many people now do not use the subjunctive after *if*, but still use this expression. Are they exceptionally applying knowledge that they do in fact have, or do they have a way of producing the expression without needing to understand why – or indeed perhaps without even noticing that – the verb takes a form they could not generate using their own linguistic system? Thirdly, what is the relationship between units of processing and words on the page? The vagaries of English writing are legion: we write *into* as one word but *out of* as two, for instance. Is *in order to* really *inorderto?* What would the implications be for viewing *take heed* as *takeheed*, since we can say *due heed was taken* and *took heed* as well? The point is not whether answers can be proffered, for they certainly can, but that any given answer reflects certain assumptions and priorities in linguistic modeling. When the questions are asked, it is these assumptions and priorities that are under examination.

The Focus of Research into Formulaic Language

Researchers of formulaic language are interested in questions such as: Why do conventionalized forms exist and persist? What determines which forms become conventionalized? What prevents or permits the replacement of one conventionalized form by another? How does the deliberate choice of a less conventionalized formulation impact on the way the message is perceived? How do children balance learning to be idiomatic with learning the underlying linguistic system that predicts so many under-used alternatives? Why do post-childhood foreign-language learners find it so difficult to identify the conventionalized nativelike form from among the many equally grammatical alternatives? What is it about common conventional word strings that makes them peculiarly resistant to the effects of aphasia?

As answers to these questions have emerged, it has become clear that the relationship between formulaic language and the language system as a whole has the potential to inform many applied linguistic endeavors, including language teaching, machine translation,

author identification and profiling, artificial speech aids, linguistic rehabilitation, and perhaps even the early diagnosis of degenerative brain conditions.

Why Formulaic Language Exists

Processing Shortcuts

Psycholinguistic evidence strongly suggests that we operate under tight processing restrictions when handling linguistic material. If this is so, then our tendency to use formulaic language might be the result of expediency – that is, it makes processing shortcuts possible. Conceptualizing a 'processing shortcut' is highly contingent on how one models psycholinguistic knowledge. However, most psycholinguists would agree that the pressure point relates to assembly rather than storage. In other words, the brain seems very able to accommodate as many lexical units as we want to store, but we are very easily thrown off course when formulating an utterance, if we try to do too many things at once.

Quite why humans should experience difficulties in composing language online is unclear, but it is probably linked to our limited working-memory capacity. In one approach to psycholinguistic modeling, formulaic language is conceived of as a solution to this constraint. It bundles a grammatical configuration of several words into a single lexical unit that can be understood or retrieved without any grammatical processing. In fact, this proposal is seriously compromised, in its extreme form, by the fact that virtually no word strings are immune from some sort of grammatical fine-tuning. In its weak form, however, the model proposes that grammatical interventions are kept to a minimum, to the benefit of processing parsimony. That is, even if it is necessary to insert the subject, verb ending, and object into *do* SOMEONE *a favor,* a saving is still made over having to retrieve each word and ending separately and combining them from scratch.

Not all psycholinguistic models, however, easily accommodate the notions of 'units' and 'assembly.' Neurologically inspired models aim to identify the processes by which pathways of neural activity are established, maintained, and used. In such models it makes no sense to speak of a word string being 'stored.' Rather, a formulaic word string is conceptualized in terms of a fast processing pathway. Just as a pianist who practices a difficult sequence of notes will, by virtue of that repetition, find it easier to play in future, so it is reasoned that if you become used to producing the articulatory movements that result in a particular routine expression, then this pathway will be strengthened, until it becomes not only fast and reliable but also rather difficult to interrupt, modify or, if it should go wrong, put back on track without starting from the beginning again. Different approaches to psycholinguistic modeling make different predictions, and so are a useful focus for investigations. By testing the predictions of each model, their relative plausibility can be evaluated.

What Formulaic Language Is Used For

Promotion of Self

There are as many different proposals about the purpose of formulaic language as there are domains in which it is found. Under one or another name, it has been independently described across a wide range of areas of linguistic research, beginning, many centuries ago, with observations in the clinical domain, and most recently blossoming as a major focus of attention in second language acquisition and teaching. In between, attention has been paid to it by researchers working on child language acquisition, sociolinguistics, literary style, phraseology, grammar, discourse, and psycholinguistics. Yet in each domain the purpose of formulaic language is differently conceived, so that a somewhat confusing picture emerges. Wray (2002) proposes that the explanation for the differences is that formulaic language is a generic strategic solution to a recurrent challenge for us as humans: how to promote our own interests.

The rationale for this proposal resides in the way that humans use language to manipulate others. Manipulation entails persuading another person to think, feel, or act in some way that you desire. Selecting linguistic material that enables you as a speaker to fluently express your message and enables your hearer(s) to easily decode it supports this self-promotional goal. For instance, commands in the army are given in a consistent, prespecified form, not only so that they will be instantly recognized, but also so that they will be acted upon as a reflex, rather than queried or challenged.

It is important to note that, in this context, it is not just the local meaning of utterances that the speaker wants the hearer to understand with ease, but also their meaning within the surrounding discourse and the pragmatic, social, and cultural context. Also, the speaker's intentions may be altruistic at one level, such as when a teacher formulates the explanation of a concept in a way that will help the students understand it. But at a deeper level even such altruism is driven by the speaker's desire to create a particular kind of outcome that is beneficial for him or herself.

Teachers want to be good at their jobs and want to avoid having to explain the same things many times. The workman who shouts a warning to a passing pedestrian certainly wants to save him or her from danger but also does not want to be responsible for injuring someone.

The following sections examine some of the various functions of formulaic language that have been chronicled in the research literature. The proposed underlying agenda of self-promotion is just a hypothesis, and it is for future researchers to establish whether it stands up to scrutiny in each of the contexts in which formulaic language is believed to operate.

A Badge of Identity

Most native speakers can think of expressions that they have picked up from someone else. Sociolinguists have long recognized that humans use language as a tool for expressing their identity relative to other speakers. When we speak, we select particular turns of phrase that we perceive to be associated with certain values, styles, and groups. We are sensitive, too, to the choices that others make. Our linguistic choices can be both conscious and subconscious and are part of a more general desire to behave like those with whom we most closely identify, or who embody our aspirations.

Social Bonding

Closely allied with the expression of identity is the selection of particular turns of phrase to achieve specific purposes in a (micro-)culturally acceptable way. For instance, in some kinds of Christian discourse, expressions like *praise the Lord* are used simultaneously as disjuncts conveying the speaker's stance towards the associated proposition(s) and as strong markers of the perceived shared values of hearer and speaker. At the macro-cultural level, native speakers within their broad speech community share certain knowledge about nativelike ways of expressing ideas – knowledge that nonnative speakers may not be party to. Becoming accepted into an adoptive speech community entails demonstrating this insider knowledge, though various dynamics relating to both the infiltrator and the host community may place obstacles in the way of a full match with native speaker knowledge.

Other kinds of social bonding also use formulaic language. For example, in Britain elaborate exchanges often take place during a simple sales transaction, with every stage accompanied by routine, largely unconscious, expressions of gratitude. Such behavior is evidently necessary to create and maintain the locally desired level of social ambience, for its absence can be interpreted as rudeness.

Memorization as an Aide-Memoire

One subtype of formulaic language consists of deliberately or inadvertently memorized material, including rhymes, prayers, speeches, songs, and so on. The deliberate memorization of texts is often associated with the need to recall the fine detail of the text correctly, not just its message or general form. It would be inappropriate, for instance, to remember only the gist of a Keats poem, so that one had to paraphrase it rather than recite it, for poetry is defined as much by the precise configuration of the form as by the meaning. Some texts, such as liturgical and legal rituals, have a performative status that can be nullified if the form is altered. Other texts must be recalled correctly because they are the key to other information. For example, it is important not to confuse which months have which numbers of days in the chant *Thirty days hath September* and not to reverse the order of the words in *Richard of York gave battle in vain* (used for remembering the colors of the rainbow), otherwise the very purpose of learning the text is defeated. The mnemonic function of formulaic language matches well the psycholinguistic notion that a formulaic word string is retrieved as a single unit, or in some automatic way. The less processing that goes on, the lower the chances of making alternative choices that undermine the integrity of the whole.

But formulaicity really comes into its own where a balance is sustained between prefabricated text and creativity. This is in evidence in oral literary traditions, where the recitation of lengthy epic poems is achieved by the strategic use of repeated text patterns to express recurrent ideas. These provide a reliable structure for a unique performance event, in which the detail of the formulation is a one-off creative variation on a traditional oral text. Key research into formulaicity in oral performance was carried out by Parry (e.g., 1930) and Lord (1960) who compared traditional Slavic poetry performances to Homer's epics. But it has also been identified in many other cultures including Anglo-Saxon, Maori, and Tibetan. Closer to home, parents retelling well-known fairy stories display something similar. Each extemporization is unique, yet fully recognizable as a version of the original. Its form is constrained both by the plot itself and by traditional, thus more or less compulsory, turns of phrase (e.g., *I'll huff and I'll puff and I'll blow your house down; Mirror, mirror on the wall, who is the fairest of them all?; Who's been sleeping in my bed?*).

Fluency Under Pressure

Public extemporization, described in the last section, must count as a high-stakes activity that can put the

performer under a lot of pressure. It seems entirely plausible that one function of repeated material in traditional narratives, as also the chorus in folk songs, is to provide the performer with processing space to remember and formulate the next part of the text. Formulaic patterns also support other kinds of fluent performance, such as auctions and sports commentaries (Kuiper, 1996). Here, as in epic poetry, familiar words and grammatical patterns aid not only the performer but also the audience. The performer can use well-rehearsed strings to relieve the pressure on productive fluency, confident that this material will come out effortlessly and without thought. Meanwhile, the audience, recognizing that a formulaic string has begun, can bypass full decoding and use the recurrent material as a means of locating and isolating what is new.

Support for First Language Acquisition

The relationship between formulaicity and language learning is complex. In first language acquisition children are known to use memorized expressions, containing grammatical constructions that are precocious relative to their current level of linguistic knowledge. However, commentators often downplay this practice relative to the acquisition of single words and grammatical rules. The reason is that while formulaic language certainly plays a social and interactional role for most children, it is unclear to what extent the early holistic learning of word strings makes any contribution to the slower, more methodical learning of the language as a system of rule-governed unit combinations. Memorized strings do seem to be broken down and reused to some extent. However, the fact that children often 'unlearn' memorized irregular forms like *went* – only to have to relearn them later – has led many researchers to regard the breaking down of formulaic material as too patchy to be a major feature of language acquisition, leaving the role of the formulas something of a puzzle.

On the other hand, since a common feature of formulaic material, both in adult and child usage, is irregularity, it is somewhat to the child's advantage **not** to be too precipitous about harvesting from a useful whole what might turn out to be rather less useful parts. In line with Peters' (1983) notion of 'segmentation,' Wray (2002) has proposed that children and adults alike take a parsimonious approach to breaking down memorized word strings. This **needs only analysis** (Wray, 2002: 130–132) enables word strings to be associated with their holistic meaning until there is direct evidence for the possibility of variation in a particular locus, when the string will be loosened in just that place, to accommodate the variation. In this way, the idiom *by and large*, which never changes, is never broken down, because there is never any input that challenges its immutable form-meaning association. As a result, neither children nor adults inform their knowledge of the word *large* by referring to its occurrence in that idiom, any more than the meaning of *king* would be informed by its apparent occurrence in *barking*. In contrast, a word string such as *pull* SOMEONE'S *leg*, which displays limited variation, will establish a balance of fixedness to flexibility that accommodates the novel subject and possessor, along with appropriate verb morphology, but retains as fixed the occurrence of *pull* and *leg*. Needs only analysis, Wray argues, accounts for the conservation of irregularity in idioms and other formulaic word strings, and, being motivated predominantly by evidence in input rather than logical potential, also explains the relative rarity of many grammatically acceptable formulations for which another formulation already exists with the same meaning.

Help and Hindrance in Second Language Acquisition

In second language acquisition, new parameters result in new patterns (see Wray, 2002: Chaps. 9–11 for a detailed review). While young children seem to acquire a second language in a manner somewhat similar to their first (and with similar success), even at kindergarten age any differences in the uses to which the language is put (and in how the child perceives it as a communicative tool) seem to affect the pattern of acquisition. As children grow older, new psychological and social constraints appear to precipitate variations in learning style and outcome, as Wong Fillmore (1979) notably found in her study of five Hispanic children in California.

By adulthood, two broad tendencies can be observed. Naturalistic learners favor approximations of large chunks gleaned from input, which may remain permanently inaccurate in form, especially if they are effective in communication. Taught learners appear to undervalue phrasal input, focusing on smaller units in order to gain a sense of control in their expression and comprehension. By the time such learners are of higher intermediate level, they characteristically display grammatically logical but often nonnativelike choices. That is, they have missed out on the acquisition of 'idiomaticity.' The challenge of how to improve nativelike idiomaticity in intermediate and advanced learners is a focus of considerable research, but no easy answers have yet materialized. An irony of attempts to promote idiomaticity through the teaching of common nativelike

expressions is that an excessive use of them can render a learner's output a somewhat meaningless concatenation of phrases, disguising other aspects of his or her linguistic knowledge. As a result, the puzzle of how to teach nativelike language is matched by the puzzle of how to test it in relation to other abilities.

A Residual Lifeline

It has been known for centuries that certain kinds of common expressions, such as greetings and curses, along with memorized rhymes, prayers, and songs, often survive when a stroke or other injury disrupts a person's linguistic abilities. In addition, individuals may produce one or more recurrent phrases peculiar to them and/or repetitive phonological strings with no apparent meaning. Psycholinguists are interested in establishing the properties shared by these resilient items, in order to shed light on linguistic processing in general. Meanwhile, clinicians and speech therapists focus on how someone with command of such a limited inventory of expressions can often succeed in conveying a great many messages, using intonation, tone of voice, and voice quality to modify or cancel the customary meaning.

Recognizing Formulaic Language

Researchers of formulaic language are currently challenged by two major practical difficulties: how to define it and how to identify it in spoken and written text. These are inevitably intertwined, for you cannot find something that remains undefined, nor define it without having examples of it. Wray (2002: Chaps. 2 and 3) explores the issues in detail, showing that many definitions confuse form, function, and meaning, while others are too exclusive or inclusive to be useful.

Frequency

One approach is to define formulaicity as a function of frequency. In this view, word strings that are often heard and said gain processing privileges born of the repetition. The increasing ease of processing reinforces their preferential selection from among the options for expressing that message. Meanwhile, their frequency is what makes them sound familiar and nativelike, so that our desire to sound like those around us encourages us to continue selecting them for social reasons. The advantage for researchers of a definition based on frequency is that it facilitates reliable identification. One can set the parameters of an automatic corpus search and extract as formulaic all the material that reaches that threshold.

There are difficulties with this approach, however. Firstly with a very few exceptions – mostly idiom adverbials and adjectives like *by and large, spick and span,* and *lock, stock, and barrel* – formulae are not invariable in form and are often not contiguous either. This complicates the searching, and while wild cards can assist in the accommodation of certain kinds of variation, the setting of the search parameters remains a significant determinant of what is included and excluded in the output and how much manual sorting is subsequently required. A second problem is where to draw the line between two formulas and two variations of one. For instance, what is the relationship between *thank you*, *thank you very much,* and *thank you very much indeed*? In practice a contingency decision is taken. But by the time readers survey the results of a study, such decisions are often long forgotten, risking the proliferation of beliefs about absolute answers rather than definition-dependent ones.

A third problem is that frequency is not determined from a consistent baseline, but rather as a function of how often a message needs to be conveyed. When we find that *good morning* is more frequent in a corpus than *long live the King* this does not tell us that the former is 'more' formulaic, only that people more often wish each other good morning than they wish the king a long life. Frequency searches therefore need to be able to measure how often a particular formulation is used to express its message. The formulaicity of *good morning* arguably owes more to its preferential use over alternatives like *good day* and *how do you do* than to its absolute frequency. Indeed, it might well be found that, opportunity for opportunity, *long live the King* is more predictable than *good morning*.

Form

Aligning formulaicity with grammatical irregularity offers an easy but rather narrow route to definition and identification. In more inclusive approaches, the cline of fixedness makes form-based definitions difficult to pin down. One strategy has been to make a feature of the variability itself, and place linguistic configurations along a continuum from fully immutable to fully flexible. Although many have favored this approach, it is difficult to avoid a descriptive taxonomy with no explanatory or predictive powers. Since there is evidently a dynamism about form, including the diachronic shift from flexible to inflexible

(fossilized), this seems a pity. Nevertheless, it is clear that form cannot be ignored. Capturing the nature and extent of the variability has also been attempted, and entails the recognition of 'frames' composed partly of lexical material and partly of abstract categories representing closed or open class choices, e.g., *NP_1 take + TENSE NP_2 to task*. Many frames become predominantly abstract, once the potential for adjectives, intensifiers, and so on is allowed for, raising new theoretical questions about just how different such frames are from traditional linguistic descriptions.

Phonological form has attracted some attention, since fluency is associated with elision, weak forms, etc., and phrases with nonliteral meanings can be expressed within a single tone unit more easily than can their literal equivalents. However, it has proved difficult to find a resilient correspondence between pronunciation and formulaicity.

Finally, in form-based accounts, the status of standard collocations remains unclear. A word may preferentially combine with particular partners without being prohibited from pairing with others. The customary pairings are unquestionably idiomatic, but often do not have other features of formulaicity.

Meaning

Some linguists regard as formulaic only expressions with a holistic meaning that cannot be derived from the individual words. A useful test of this is to swap an individual word with a near synonym, to see if this destroys some feature of the meaning. The results can be very informative: the *large intestine* is not the same as the *big intestine* nor the *big toe* as the *large toe*. However, it is easy to cross into instances where the alternative is not really a synonym. In *by and large* the word *large* does not, and never did, relate to size, and this is why **by and big* sounds impossible.

Holistic-level semantics is, however, not a sufficiently broad definer of formulaicity. Even if the definition is extended to cover the pragmatics of the whole, as with expressions like *have a nice day*, difficulties arise. The expression *great to see you again* will, for example, fall outside of the definition, being neither opaque nor endued with a strong pragmatic tone. A second difficulty is that there is no cleardividing line between what is and is not opaque. Several dynamics interact here, including the survival in a formula of an outmoded word (e.g., *curry favor*) and the use of metaphor (e.g., *straight from the horse's mouth*). Just as with morphology and etymology in word formation, what is opaque for one person may be transparent for another. It follows that any attempt to define formulaic language in relation to meaning cannot ignore the knowledge of the individual. Yet drawing on the individual's intuition and judgment as the basis for defining and identifying formulaic language runs into its own serious problems.

All in all, it remains difficult to characterise formulaic language in purely semantic terms, and, again, it is part of the researcher's job to formulate theory that can explain why this should be so.

Future Directions

Research into formulaic language draws together the theoretical and the practical. In applied spheres it is possible to by-pass theory, but understanding how formulaic language fits into the bigger picture remains important. So far, the modeling of formulaic language has been psycholinguistically inspired, but the role of psycholinguistic models in informing linguistic theory has always been debated. The point of contact must be the definition of the lexical unit, on the one hand, and of the word and morpheme, on the other. Cross-linguistic research already questions the viability of the 'word' as a linguistic category (e.g., Dixon and Aikhenvald, 2002), and research on formulaic language suggests that words are not the largest units being manipulated by the grammar. While some theoretical linguists maintain that idiomaticity falls outside the domain of formal linguistic description, there is undoubtedly scope for theory to address more directly the question of what formulaic language is and how it arises.

Formulaic Speech

K Kuiper, University of Canterbury, Christchurch, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Formulaic speech is simply speech that utilizes formulae. Formulae are phrasal lexical items that are indexed for their role in social interaction or, more narrowly, indexed for specific use in discourse varieties, registers, and genres. (This sense of the word formula should be distinguished from the more general sense of the word to denote mathematical or logical expressions.) As for speech, it is to be distinguished from language in the sense that speaking is a variety of linguistic performance, what humans do with language, not language itself, which is a knowledge system. Knowledge systems contain both declarative and procedural knowledge. Declarative knowledge is knowledge about 'what' – for example, the fact that all lower-body garments that have two pipes, such as *trousers* and *knickerbockers*, are plural in English. This fact can be regarded as as part of a native speaker's declarative knowledge of English. Linguistic competence is mostly of this kind. Procedural knowledge is knowledge about 'how to': for example, how to behave verbally at dinner parties and in church is partly based on procedural knowledge. Formulae are part of the declarative knowledge of a language that speakers have, and speakers also have procedural knowledge about how they are used.

The Phrasal Lexicon

All linguistic performance draws on the lexicon. Formulaic speech draws on the phrasal lexicon. For example, the performative sentence *I name this ship the… God bless her and all who sail in her* is a formula in that those who know it know the conditions under which it may be appropriately uttered (Austin, 1976). Some single-word lexical items also have such usage properties (Wray, 2002: 264). One-word curses, for example, have specific contexts of use. They are used to express one's adverse reaction to entities or events. They are to be used in some social domains and not others. Polite curses such as *Darn!* are used in contexts where *Shit!* might be inappropriate. Some linguists would include such one-word items within the definition of formulae, but usually formulae are regarded as being phrasal.

A number of formulaic performatives, such as the ship-launching-and-naming formula, have been thoroughly analyzed. Those who know such a formula not only know it as a form of words, i.e., as a lexicalized phrase, but also know that it is associated with a matrix of social conditions that must be fulfilled for it to function in its socially prescribed manner (Coulmas, 1979). The speaker must be the person designated, by those in authority over the launching, to be the person to speak these words. The person must speak the formula at the time and place designated for the naming and launching ceremony. She must also break a bottle of champagne over the bow of the ship, and so forth. If there is a mismatch between what native speakers know to be the prescribed conditions of use for the formula and the context in which a speaker is using the formula, various effects may occur. For example, uttering the launching formulae the day before the official launch when one is not the person designated to perform the launch does not count as a ship launching and can create effects such as eliciting laughter if there are others present. In other contexts, using formulae inappropriately can have more serious consequences, such being committed to a psychiatric institution or to prison for uttering obscene curses at police officers without any cause (and sometimes even when one does have cause).

Formulaic Speech

K Kuiper, University of Canterbury, Christchurch, New Zealand

Introduction

Formulaic speech is simply speech that utilizes formulae. Formulae are phrasal lexical items that are indexed for their role in social interaction or, more narrowly, indexed for specific use in discourse varieties, registers, and genres. (This sense of the word formula should be distinguished from the more general sense of the word to denote mathematical or logical expressions.) As for speech, it is to be distinguished from language in the sense that speaking is a variety of linguistic performance, what humans do with language, not language itself, which is a knowledge system. Knowledge systems contain both declarative and procedural knowledge. Declarative knowledge is knowledge about 'what' – for example, the fact that all lower-body garments that have two pipes, such as *trousers* and *knickerbockers*, are plural in English. This fact can be regarded as as part of a native speaker's declarative knowledge of English. Linguistic competence is mostly of this kind. Procedural knowledge is knowledge about 'how to': for example, how to behave verbally at dinner parties and in church is partly based on procedural knowledge. Formulae are part of the declarative knowledge of a language that speakers have, and speakers also have procedural knowledge about how they are used.

The Phrasal Lexicon

All linguistic performance draws on the lexicon. Formulaic speech draws on the phrasal lexicon. For example, the performative sentence *I name this ship the… God bless her and all who sail in her* is a formula in that those who know it know the conditions under which it may be appropriately uttered (Austin, 1976). Some single-word lexical items also have such usage properties (Wray, 2002: 264). One-word curses, for example, have specific contexts of use. They are used to express one's adverse reaction to entities or events. They are to be used in some social domains and not others. Polite curses such as *Darn!* are used in contexts where *Shit!* might be inappropriate. Some linguists would include such one-word items within the definition of formulae, but usually formulae are regarded as being phrasal.

A number of formulaic performatives, such as the ship-launching-and-naming formula, have been thoroughly analyzed. Those who know such a formula not only know it as a form of words, i.e., as a lexicalized phrase, but also know that it is associated with a matrix of social conditions that must be fulfilled for it to function in its socially prescribed manner (Coulmas, 1979). The speaker must be the person designated, by those in authority over the launching, to be the person to speak these words. The person must speak the formula at the time and place designated for the naming and launching ceremony. She must also break a bottle of champagne over the bow of the ship, and so forth. If there is a mismatch between what native speakers know to be the prescribed conditions of use for the formula and the context in which a speaker is using the formula, various effects may occur. For example, uttering the launching formulae the day before the official launch when one is not the person designated to perform the launch does not count as a ship launching and can create effects such as eliciting laughter if there are others present. In other contexts, using formulae inappropriately can have more serious consequences, such being committed to a psychiatric institution or to prison for uttering obscene curses at police officers without any cause (and sometimes even when one does have cause).

Classic Formulaic Speech

As an object of a research program, formulaic speech came into its own with the publication of Albert Bates Lord's book *The singer of tales* (Lord, 1960). Lord's approach also provided many of the leading ideas that have borne fruit in subsequent work. Lord's book was the culmination of years of fieldwork, in what was then Yugoslavia, investigating how the oral heroic South Slavic epics were being performed. The aim was to come to an understanding of how the poems attributed to Homer might have come into being. Lord and his senior partner, Milman Parry, were the first to record oral traditional poets, which they did with primitive wire recording equipment.

The performance of South Slavic epic occurs in particular places and at particular times, notably in coffeehouses during Ramadan. Bards perform under contract to the owner of the *kafana*, and the best can provide a new epic for each of the 30 nights of Ramadan. The defining characteristic of the performances of such bards is of composition in performance. The epic is composed anew each time it is performed and is therefore never exactly the same each time it is performed. To put it differently, bards do not recall epics verbatim but compose them from elements that are common in the tradition to which they are heir. The traditional elements are of three kinds.

The first element is a set of plots, broad outlines of stories. Klaeber (1950) proposed that the basic plot of *Beowulf*, itself an oral heroic poem, consists of two sections: Beowulf's early heroic actions and then his last actions. In the first, Beowulf fights and defeats Grendel and then fights and defeats Grendel's mother. In the second, Beowulf fights the dragon, kills it, and is himself mortally wounded in the attempt. Each of these in turn has substructure, but the plot is basically a serial structure with some additional embedded material. It can, however, be amplified in performance and expanded. Episodes can be added from a store of episodes the bard knows. Episodes can also be deleted if an audience proves unsympathetic.

The second element of a composition in performance are the episodes themselves, of which there are also a finite number. In the *Iliad*, warriors arm themselves before battle. This small episode is conventionally ordered, and the events it consists of are normally given in the same order. In South Slavic epics, the meeting of the council always introduces the actors in the same order. Heroes leave for battle and their leave-taking has a similar episodic character each time it is related.

The final elements are the formulae out of which the oral text is ultimately composed. Formulae in oral epic traditions are forms of words that conform to the metrical tradition within which the performer is brought up. In the case of Homer, formulae must fit the hexameter template of the Homeric tradition. In the case of the Old English tradition, they must conform to the pattern of half-lines that have two stressed syllables and that alliterate. As forms of words, some formulae are wholly fixed, but others allow for a small amount of internal variation in that there might be two or three words that can occupy a particular position in the phrase.

These traditional resources are part of an oral tradition. They are the linguistic knowledge that underlies the performances of bards who sing in a tradition. There are other requirements, such as the capacity to perform fluently, to sing or chant in the traditional way, to be responsive to an audience, and to fill the time available by adjusting the length of the performance. The totality of these capacities might be termed the generalized communicative competence of the tradition.

How do bards acquire this kind of communicative competence? According to Lord, the process is a three-stage one, beginning with an apprenticeship where a novice attaches himself to a master or masters and spends as much time as possible listening to them. Then follows a period as journeyman, where a singer can produce a series of songs but relatively stereotypically and without great flexibility. Finally, and not for all performers, there is a period of mastery where the performer can learn new songs quickly, adapt himself to local conditions, and create new formulae by adapting the old. The result is that masters are acknowledged by all as such and are much sought after as performers. In the case of Old English heroic poetry, one feels that the bard who composed the fragment of the *Fight at Finnsburg* would have had particular narrative strengths as a performer. There is a qualitative dimension, then, to performance in an oral-formulaic tradition.

Two sets of determinants lead to the creation of oral-formulaic traditions. The first set is social. Formulaic traditions exist in particular speech communities and serve particular functions. Germanic bards performed in the mead halls before warrior bands and their chiefs, not in coffeehouses to people who were fasting for Ramadan. Germanic traditions dealt with Germanic heroes from the past and within a heroic code different in its details from the heroic code of the South Slavic epics. The exploration of these traditions has been the subject of ongoing

research since the publication of *The singer of tales* (Foley, 1990).

The second set of determinants is psycholinguistic. Live performance requires memory and processing resources. The three sets of linguistic resources Lord proposes for oral traditional performance all serve the function of cutting down the amount of information a speaker has to keep in memory and to process while performing. Since all formulae are indexed for the task they perform in the discourse – such as announcing the entrance of the cupbearer at a council meeting – when a performer must relate the entrance of the cupbearer, the formulae for saying that are in memory and do not need to be constructed *ab novo*. The plots are already known, as are the episodes from which the performances are constructed. The performer still has to keep track of where the story is currently located in the plot as a whole, but once he or she has embarked on an episode such as a Homeric battle, its progress is controlled partly by the required sequence of such episodes and partly by the formulae themselves, since they have rich associative networks with those in their conventional proximity.

Since these resources are in many traditions carried down the generations entirely by oral means, the relative stability of the traditions over time is perhaps surprising. Most forms of words are not long remembered. Humans are good at recalling the gist of what they have heard, but not the form of words within which it was couched. However, Rubin (1995) showed just how durable oral traditions can be and why. Formulae contain a large number of mnemonic 'hooks,' which allow them to be recalled accurately over very long periods. There is also a considerable social investment in having these traditions presented in a consistent way over time. Oral cultures are like that. So are the oral cultures within literate cultures. The formulae used by the speaker of a parliament are invested with the power of the office, and a speaker must use his or her formulae, which are also the formulae of the office, with panache to control members and the proceedings of a house of parliament.

Classic formulaic speech does not require accurate verbatim recall. Variation is possible, and innovation within a tradition can be valued. Fry (1975) showed how Caedmon used the pagan formulaic tradition of Old English heroic poetry to create a hymn of praise to the Christian God with a minimum of adaptation. However, the adaptation was significant. There are, on the other hand, cultures where accurate verbatim recall is also important. The laws of preliterate Iceland rested on the capacity to plead a case with totally accurate recall. If that was not done, the case failed.

Formulae in Other Forms of Speech

Classic oral formulaic speech of the kind documented by Lord for the performance of South Slavic epics, and now found to be at the core of many other oral literary traditions, is not limited to such traditions but may also be found in a large range of vernacular traditions (Edwards and Sienkewicz, 1990). These range from single performative formulae, such as *I now declare you man and wife*, through dyadic formulaic pairs such as *How are you? – Fine, thanks*, to traditions that are not as clearly governed by discourse structure rules and where not every sentence is a formula. For example, Pawley (1991) showed that at cricket's most ritual moment, the bowling of the ball and its immediate aftermath, cricket commentators are highly formulaic. However, at other times, they converse relatively less formulaically about the weather, the spectators, and even seagulls. At this point, formulaic speech shades off into speech that may contain phrasal lexical items of various sorts but that are not necessarily indexed for their social or discourse role. Intermediate situations include formulae used as discourse markers or politeness signals in otherwise nonformulaic speech (Aijmer, 1996; Ferguson, 1976; Keller, 1981).

When we look at such 'in-between' uses of formulae, the weight of two sets of factors, social and psycholinguistic, is in many cases hard to assess. The psycholinguistic factors have been investigated in the cases of auctioneers and sports commentators (Kuiper, 1996). These performers operate within their own oral traditions, and they produce performances that have many of the characteristics of those of Lord's bards. However, the conditions under which they do so vary. Slow auctions do not place great pressure on the auctioneer, while fast ones do. Slow sports allow a lot of time for constructing speech, whereas fast ones do not. It seems that classic formulaic speech – that is, speech with a fixed discourse structure, high frequency of formulae, and unusual fluency – is most in evidence where performers are subject to high memory and processing pressure but where it cannot take place unless the performances are ritualized to some extent, that is, they have a continuity over time and are socially embedded in some way. Traditional Maori *marae* ritual is of this kind (Salmond, 1977). Recent research into psycholinguistic aspects of formulaic speech can be found in Schmitt (2004).

It may be that the social embeddedness of formulaic speech allows one to analyze further the social context in terms of the function of the rituals that formulaic speech can enact. But that need not inevitably yield interesting ethnographic

interpretations. Many social practices exist because they are traditional rather than because they have clear sociocultural functions. Some communities of practice shake hands; some press noses. That humans greet one another is common to the human condition, but one need not and sometimes cannot read major symbolic significance into how that is done. On the other hand, routine human behavior that involves formulaic talk is frequently tuned in to particular sociocultural norms and therefore can yield worthwhile ethnographic interpretations. There are cultural practices of significance that are implemented in whole or part through formulaic speech. This has been known since Malinowski's ethnographies in Melanesia (Malinowski, 1922). Much of what Malinowski observed could be understood only through an understanding of the formulaic performances surrounding it. Rites of passage, for example, are normally accompanied by formulaic speech. The cultural import of the ritual can be understood better if the speech and its formulae are understood in their context. With weddings, for example, the traditional formulaic vows declare publicly, whatever the participants' private intentions, that their future relationship will be monogamous and lifelong. That is the tacit Judeo-Christian assumption behind these vows. Ritual insult can be similarly analyzed for what it has to say about male bonding (Dundes *et al.*, 1972; Kuiper, 1990; Labov, 1972). Proverbs that qualify as formulae on the grounds of their use in particular social contexts were revealingly analyzed as political tools by Mieder (1997) and Ji (2004). Essays exploring the relationships between formulaic speech and its cultural context can be found in Skandera (in press).

Formulae as PLIs

Phrasal lexical items (PLIs) have linguistic properties besides, in some instances, having associated conditions of use (Burger, 2003: 11–123). They can, for example, be classified as idioms. For instance, the auctioneer's formula *going once, going twice* does not actually mean literally that the lot is being sold one, twice, or three times. It is being sold only once. In this way the presale formula is like *tug at NP's heartstrings* or *make heavy weather of NP*, which are generally taken to be semantically noncompositional phrasal lexical items. Formulae might also be classified as restricted collocations in having arbitrary restrictions on which words pattern with which. For example, the auctioning formulae *last call* cannot have any word other than *call* used in second position. Auctioneers do not say *last shout* or *last invitation* to indicate that they are about to close the bidding. In this way, many formulae are like prepositional usage in English, which frequently involves collocational restrictions. One takes notice *of* something; one takes an interest *in* something. One does not take notice *in* something or an interest *of* something. These other properties have no bearing on whether or not a phrasal lexical item is a formula, but they clearly cross-classify with the property of being a formula. The general area of phraseology was surveyed from a variety of perspectives in Everaert *et al.* (1995), Cowie (1998), and Burger *et al.* (in press).

The Size of the Formulaic Vocabulary

Since formulae are PLIs, it is an interesting question how many items a native speaker knows. This question has not been answered with any degree of specificity. Estimates as to the size of the phrasal lexicon in general range from its being of the same order of magnitude as the single-word lexicon (Becker, 1975: 29; Jackendoff, 1995: 137) to an order of magnitude larger (Mel'čuk, 1995: 169). Often those making such estimates do not indicate whether the numbers are those of PLIs in a language or in the lexicon of an individual speaker or both. How many of these items are formulae in either case is not normally estimated. However, the task, in the case of classical formulaic speech, is certainly a possible one. By collecting sufficient recordings, one can isolate the formulae of the tradition and their variant forms. In rich traditions, the formulaic vocabulary of a mature performer would certainly run into hundreds and thousands of items. Sports commentators are heirs to such rich traditions, as, clearly, are the performers of heroic epics. This suggests that the most productive approach is to see speakers as heteroglossic in the Bakhtinian sense (Bakhtin, 1981). The crucial factor is not how many formulae a speaker knows but the traditions in which the speaker is fluent. Each of these traditions will have its own formulae. A speaker's communicative competence is thus the repertoire of speaker roles in which he or she is communicatively competent. The formulaic vocabulary known in each of these roles then becomes a manifestation of this kind of competence.

Formulaic Speech and Linguistic Variation

Formulaic speech is not in general a case of dialectal variation, since mature native speakers may switch into and out of formulaic speech varieties. It is, rather, a manifestation of register or genre variation. Exactly what the parameters of situational constraint are can be examined only on a case-by-case basis.

Figure 1 Wrightson livestock auctioneer in action, Oxford ewe fair. (Photo by Koenraad Kuiper, 1998.)

The situation of supermarket checkout operators surely has little socially in common with that of Old English bards. Yet both produce formulaic speech. This suggests that careful ethnographic description is needed of each social situation in which a formulaic tradition is found.

Within each tradition there may be variation. Different geographic areas can develop local variants of a tradition. In the case of auctions, different livestock saleyards have their own local variants of the linguistic features of the variety, including the discourse structure rules, formulae, and prosodics (Figure 1). American tobacco auctioneers chant with Black musical ornamentation, and their formulaic inventory includes formulae such as *Dance with me darlin's*. Auctioneers at Sotheby's do not chant their auctions with Black musical ornamentation and do not use the formula *Dance with me darlin's* (Kuiper and Tillis, 1986). Different commodity markets have theirs. The formula *Farm x is a footrot-free property* belongs to livestock auctions where sheep are sold in New Zealand and not to auctions of houses. There is, therefore, dialect variation within a tradition. All performers change their performances over time and develop their own idiosyncrasies. Variation within formulaic traditions thus also has both a diachronic and an idiolectal dimension. Again, the nature of this variation can be uncovered only by looking in detail at each tradition.

Formulaic and Other Speech

The observation that much of naturally occurring speech is formulaic to a degree is sometimes taken as evidence against the Chomskian position that human linguistic capacity is creative. That does not follow. Human linguistic potential is fully as Chomsky regards it. That this potential is not fully or partially brought into play in some varieties of speech is not counterevidence to this position. It is counterevidence to the position that every sentence humans utter is a novel creation (Becker, 1975). The interesting question that remains is how much of human linguistic potential rests on recall and how much on the processing of novel utterances. This is likely to be contextually determined, and the two factors that govern formulaic speech – namely, psycholinguistic factors to do with memory and processing pressures and sociocultural factors such as the degree to which the situation in which the speaker is speaking is routine – are likely to be the major determinants. In ritual contexts and under pressure, such as when composing prayers of intercession, speakers are likely to be able to draw on formulaic resources. Where there is time, and novelty is required, such as in the writing of poems, formulaic speech is less likely.

Foucault, Michel (1926–1984)

T P Górski, Uniwersytet Wroclawski, Wroclaw, Poland

© 2006 Elsevier Ltd. All rights reserved.

Michel Foucault (true name Paul, born on October 15, 1926, in Poitiers, France) was a French philosopher, psychologist, and psychopathologist. He graduated from the École Normale Supérieure de Paris in 1952. From 1954 to 1958 he taught French at the University of Uppsala in Sweden, and from 1958–1959 at the University of Warsaw, Poland, where he established the Center of French Culture. Foucault spent the following year in Hamburg, returned to France in 1960, and became the head of the Department of Philosophy at the University of Clermont-Ferrard. In 1969, he was given a professor title and was promoted to the head of the History of Systems of Thought at the College de France. Foucault died of AIDS on June 25, 1984.

Foucault's ideas developed in three periods marked by the issue of his major books.

The first period, represented by *Madness and civilization* (Foucault's doctoral dissertation) is inspired by the fact that madness, though originally inspired divinely, was considered a mental illness and thus simultaneously repressed in the Western societies. He also claimed that madness contrasted to sanity, and the repercussion caused by this distinction is a troublesome and scalding conception dating back to the Age of Reason.

In the second period of his development, Foucault issued *L'Ordre du discours*, which is a seminal study of the natural sciences, linguistics, economics, and social thought of the 18th and 19th centuries. Greatly

ethnography of communication. New York: Holt, Rinehart and Winston. 130–160.

Foucault, Michel (1926–1984)

T P Górski, Uniwersytet Wroclawski, Wroclaw, Poland

© 2006 Elsevier Ltd. All rights reserved.

Michel Foucault (true name Paul, born on October 15, 1926, in Poitiers, France) was a French philosopher, psychologist, and psychopathologist. He graduated from the École Normale Supérieure de Paris in 1952. From 1954 to 1958 he taught French at the University of Uppsala in Sweden, and from 1958–1959 at the University of Warsaw, Poland, where he established the Center of French Culture. Foucault spent the following year in Hamburg, returned to France in 1960, and became the head of the Department of Philosophy at the University of Clermont-Ferrard. In 1969, he was given a professor title and was promoted to the head of the History of Systems of Thought at the College de France. Foucault died of AIDS on June 25, 1984.

Foucault's ideas developed in three periods marked by the issue of his major books.

The first period, represented by *Madness and civilization* (Foucault's doctoral dissertation) is inspired by the fact that madness, though originally inspired divinely, was considered a mental illness and thus simultaneously repressed in the Western societies. He also claimed that madness contrasted to sanity, and the repercussion caused by this distinction is a troublesome and scalding conception dating back to the Age of Reason.

In the second period of his development, Foucault issued *L'Ordre du discours*, which is a seminal study of the natural sciences, linguistics, economics, and social thought of the 18th and 19th centuries. Greatly

inspired by Nietzsche's claim about the death of God, Foucault declares the death of Man – a discursive formation of the advances in sciences in the last 150 years.

During the last period (from 1975), Foucault examined the effects of power on the individuals and society, and demonstrated how historical inquiry are combined with philosophical questions about subjectivity, knowledge, and power. He showed how sexuality can be put into discourse and argued that simple liberation from power is impossible. Subjectivity, he claims, can be viewed through one's sexuality. In the immense three-volume study entitled *Histoire de la sexualite* (the first two volumes were issued during his lifetime; the third one is unfinished) he gives an insight into the understanding of sexuality through centuries, and how Western Societies perceived themselves as sexual beings.

Foucault juxtaposes the 'history of ideas' with the 'archeology of science.' In the 'speaking' of language, he sees the replication of discourses of power; what constitutes us as human speakers is social power, hegemony, and ideology. He claims that the history of thought, of knowledge, of philosophy, of literature seems to be seeking and discovering discontinuities. Foucault considers all knowledge arbitrary, including notions of truth, in order to keep power structures relevant and functioning. In this view, he rejects the linear model of history and suggests analyses of discourse, its relative rules in various moments of history, and sees any form of writing or expressing oneself as the way of abandoning of disruptions in favor of stable structures. Moreover, he sees discourse not as a document, but as a monument.

Foucault was not only philosopher, lecturer, and writer, but also participated in the political actions; he actively helped the Solidarność [Solidarity] party in Poland in 1980 and engaged in the movements against discrimination of the disabled, homosexual, and marginal social groups. His thoughts, taken over in the 1990s by the queer theory, became the source of the revival of the feminist, gay, and lesbian studies.

Fowler, Henry Watson (1858–1933)

E McKean, VERBATIM: The Language Quarterly

© 2006 Elsevier Ltd. All rights reserved.

Fowler is the name by which most people refer to H. W. Fowler's (1858–1933) landmark book, *A Dictionary of modern English usage* (*MEU,* first edition, 1926). Oxford University Press sensibly rejected Fowler's suggestion that the book be called '*Oxford Pedantics*.'

Fowler was born in Kent, England and attended Rugby School and Balliol College in Oxford. After leaving Oxford, he worked as a schoolteacher, first in Scotland (1881–1882), and then in Yorkshire from 1882–1899. He then moved to London to work as a journalist, living mainly on his inheritance from his father. H. W. Fowler was a shy and reserved man who took great pleasure in daily exercise, especially cold-water swimming.

In 1903, Fowler moved to the parish of St Peter-in-the-Wood, Guernsey, to join his brother, Francis George (Frank) Fowler. They lived in side-by-side granite cottages, and worked together translating the works of the Greek writer Lucian of Samosata for the Clarendon Press, which published them in four volumes in 1905. *The King's English* (1906), which Fowler described as "a sort of English composition manual, from the negative point of view, for journalists and amateur writers," was published with only their initials, but its authorship was soon

inspired by Nietzsche's claim about the death of God, Foucault declares the death of Man – a discursive formation of the advances in sciences in the last 150 years.

During the last period (from 1975), Foucault examined the effects of power on the individuals and society, and demonstrated how historical inquiry are combined with philosophical questions about subjectivity, knowledge, and power. He showed how sexuality can be put into discourse and argued that simple liberation from power is impossible. Subjectivity, he claims, can be viewed through one's sexuality. In the immense three-volume study entitled *Histoire de la sexualite* (the first two volumes were issued during his lifetime; the third one is unfinished) he gives an insight into the understanding of sexuality through centuries, and how Western Societies perceived themselves as sexual beings.

Foucault juxtaposes the 'history of ideas' with the 'archeology of science.' Fowler is the name by which most people refer to H. W. Fowler's (1858–1933) landmark book, *A Dictionary of modern English usage* (*MEU,* first edition, 1926). Oxford University Press sensibly rejected Fowler's suggestion that the book be called '*Oxford Pedantics*.'

Fowler was born in Kent, England and attended Rugby School and Balliol College in Oxford. After leaving Oxford, he worked as a schoolteacher, first in Scotland (1881–1882), and then in Yorkshire from 1882–1899. He then moved to London to work as a journalist, living mainly on his inheritance from his father. H. W. Fowler was a shy and reserved man who took great pleasure in daily exercise, especially cold-water swimming.

In 1903, Fowler moved to the parish of St Peter-in-the-Wood, Guernsey, to join his brother, Francis George (Frank) Fowler. They lived in side-by-side granite cottages, and worked together translating the works of the Greek writer Lucian of Samosata for the Clarendon Press, which published them in four volumes in 1905. *The King's English* (1906), which Fowler described as "a sort of English composition manual, from the negative point of view, for journalists and amateur writers," was published with only their initials, but its authorship was soon

guessed. Some reviewers took issue with a few of their pronouncements, especially their condemning as 'superstition' the stricture against ending a clause or sentence with a preposition.

The brothers then turned to *The concise Oxford dictionary of current English (COD)*. Completed in 1911, the dictionary was very successful, both in the UK and overseas, despite Fowler's lack of experience in lexicography. As Fowler put it in the preface to the second edition of *COD*, they had been "plunging into the sea of lexicography without having been first taught to swim." They clashed more than occasionally with Oxford editors on matters of spelling, pronunciation, and definition, but not about payment – Fowler and his brother received only lump sums for their work for Oxford, not royalties, and Fowler several times said that he believed that he was being overpaid for his efforts.

Tired of lexicography, Fowler returned to a project he had suggested to OUP years before, an 'idiom dictionary,' that would only deal with words for which there were difficulties of usage. This was the project that became *MEU*. Work on *MEU* was interrupted by World War I, when Fowler at age 56, and his brother at age 45, enlisted. Put in support positions, neither brother saw much action, and they were invalided out of the army. Frank died of tuberculosis in 1918, and Fowler carried on alone, working on the *Pocket Oxford dictionary* (1924) and a second edition of *The concise Oxford dictionary of current English (COD,* 1929).

Fowler, although a gifted classical scholar, was not a linguist, and his pronouncements in *MEU* are those of a prescriptive (albeit very entertaining) schoolteacher. His goal was to be "more courageous" than lexicographers in declaring what was and what was not idiomatic British English, to be a guide for the "half-educated Englishman" who needed to know "Can I say so-and-so"?

Fowler, Roger (b. 1938)

W Downes, University of East Anglia, Norwich, UK

© 2006 Elsevier Ltd. All rights reserved.

Roger Fowler was born on August 23, 1938, in humble circumstances in Worcestershire, England. He was educated first at Tewkesbury Grammar School and then at University College London, from which he received his M.A. in English in 1962. He lectured first at the University of Hull, 1960–1964, moving to the newly founded University of East Anglia (UEA), Norwich, where he remained – except for sabbaticals to Berkeley and Brown – until his sudden untimely death on June 20, 1999.

Having read the English 'language syllabus' in London, Fowler began as a mediaevalist. His 1962 M.A. thesis, an annotated edition of Wulfstan's *Canons of Edgar*, was published in 1972. However, by the mid-1960s he had become a key advocate of the new relation between modern linguistics and literature in English Studies. He preferred the term 'linguistic criticism' to 'stylistics,' which he used in a restricted technical sense. From the mid-1970s, he became known as one of the founders of an overtly political and controversial 'critical linguistics,' an extension of these methods to the revelatory critique of ideology in language use. Writing or editing more than 20 books, his thinking was influential for many practitioners of both literary and critical linguistics, inventively showing what was possible in both these areas.

Stimulated on the one hand by the attention to the language of literature in New and Practical Criticism – he admired Nowottny's 1962 *The language poet's use* – and on the other hand by the possibilities of linguistics as a precise and objective tool, Fowler early argued that literary criticism and education needed linguistics to address language in a rigorous, rather than an impressionistic way, and to make serious advances in some technical areas, such as metrics. His sustained thinking about this relationship can be traced from the 1966 volume he edited, through the seminal collections of his articles in *The languages of*

guessed. Some reviewers took issue with a few of their pronouncements, especially their condemning as 'superstition' the stricture against ending a clause or sentence with a preposition.

Fowler, Roger (b. 1938)

W Downes, University of East Anglia, Norwich, UK

© 2006 Elsevier Ltd. All rights reserved.

Roger Fowler was born on August 23, 1938, in humble circumstances in Worcestershire, England. He was educated first at Tewkesbury Grammar School and then at University College London, from which he received his M.A. in English in 1962. He lectured first at the University of Hull, 1960–1964, moving to the newly founded University of East Anglia (UEA), Norwich, where he remained – except for sabbaticals to Berkeley and Brown – until his sudden untimely death on June 20, 1999.

Having read the English 'language syllabus' in London, Fowler began as a mediaevalist. His 1962 M.A. thesis, an annotated edition of Wulfstan's *Canons of Edgar*, was published in 1972. However, by the mid-1960s he had become a key advocate of the new relation between modern linguistics and literature in English Studies. He preferred the term 'linguistic criticism' to 'stylistics,' which he used in a restricted technical sense. From the mid-1970s, he became known as one of the founders of an overtly political and controversial 'critical linguistics,' an extension of these methods to the revelatory critique of ideology in language use. Writing or editing more than 20 books, his thinking was influential for many practitioners of both literary and critical linguistics, inventively showing what was possible in both these areas.

Stimulated on the one hand by the attention to the language of literature in New and Practical Criticism – he admired Nowottny's 1962 *The language poet's use* – and on the other hand by the possibilities of linguistics as a precise and objective tool, Fowler early argued that literary criticism and education needed linguistics to address language in a rigorous, rather than an impressionistic way, and to make serious advances in some technical areas, such as metrics. His sustained thinking about this relationship can be traced from the 1966 volume he edited, through the seminal collections of his articles in *The languages of*

literature (1971) and *Literature as social discourse* (1981) to the second edition of *Linguistic criticism* (1996a), a book designed to make his method widely accessible. In *Linguistics and the novel* (1971), which introduced the concept of 'mind style,' Fowler was influential in developing the linguistic criticism of this genre. He confronted head-on the conflict between the literary and language/linguistic sides of English Studies and the abiding hostility of some to the methodological claims of linguistics in the humanities. (He himself was transferred out of UEA's School of English in 1996 and the linguistics degree he founded was abolished in 2004.) In the 1971 volume, this issue is aired in a debate with the critic F. W. Bateson. Fowler expressed exasperation at the reciprocal ignorance and acrimony of this 'schism within English Studies.' His own approach as an 'interdisciplinary linguist' was flexible and open-minded, rejecting both exaggerated claims for linguistics – as well as being eclectic/pragmatic as to what linguistics to deploy – and what he viewed as elitist obscurantism or inaccuracy about language in much literary criticism.

Early on, Fowler distinguishes between brute linguistic description of texts – of limited interest to criticism – and higher 'levels of achievement.' These involve the interpretation of described patterns. A second level is 'stylistics,' the isolation of stable linguistic patterns characteristic of periods or authors. The critical use of linguistics is different again. At this third level, the linguist acts as critic, forming interpretative hypotheses as part of the intuitive literary activity of criticism, approaching texts with literary hunches. This is 'linguistic criticism.' And it emphatically provides no mechanical method or discovery procedure for reading. Instead, it allows for rigor and objectivity in the formulation of and argument for or against literarily informed readings.

From the mid-1970s, Fowler's linguistics becomes less formal and, influenced by both M. A. K. Halliday and developments in sociolinguistics and pragmatics, more social, contextual, and functional (Fowler, 1981, 1986, 1990). He is instrumental in promoting the theories of M. Bakhtin and V. N. Voloshinov (e.g., Fowler, 1983) and employing Halliday's notion of 'anti-language' (e.g., Fowler, 1979a). He poses the question: What motivates the stylistic choices that constitute the linguistic pattern of the text? The answer is the way the text constitutes and reproduces the social context of its production and consumption within the wider society. Linguistic criticism is an interpretative procedure that demonstrates this process for all to see; and such criticism is itself defamiliarizing.

This sociolinguistic turn has consequences for his literary theory. In the 1982 volume, Fowler asserts – against Jakobson's poetics – that there is no essentialist answer to the question, What is literature? Instead, as he says in his 1975–1976 Royal Institute of Philosophy lecture, "What literature is, can be stated empirically, within the realm of sociolinguistic fact. It is an open set of texts, of great formal diversity, recognized by a culture as possessing certain institutional values and performing certain functions" (reprinted in Fowler, 1982: 81). The values derive from the function of such texts in society. In this respect, literary texts are not in principle different from other text types. Therefore, linguistic criticism as a method equally applies to texts of all kinds. All texts are both products of and processes within social practice and are equally subject to a critique that reveals this. (The anti-esthetic point that there is no qualitative distinctiveness in literature was made as early as 1971. See Fowler, 1971: 16.)

This move reflects the fact that Fowler and his associates, Gunther Kress, Robert Hodge, Tony Trew, and others, had been employing linguistic methods in a radical social critique of institutional and media texts; see the collective 1979 volume *Language and control*. (For criticism of this approach see Pateman, 1981.) In this politically committed 'Critical Linguistics,' Fowler *et al.* (1979) show how stylistic patterns are motivated ideologically. (He refers to Althusser, 1971 as a source for his notions of ideology and legitimation.) But for Fowler, 'ideology' simply means that the language used in social practices necessarily reflects tacit beliefs that, although contingent expressions of social structure and its processes of power, present themselves as natural, as unchallengeable common sense. The critic's job is to 'see through' this ideological 'representedness' by displaying how it is linguistically achieved. In Fowler's version of 'weak Whorfianism' – largely derived from Berger and Luckmann (1976) – the critic penetrates the artificiality of representation, not to reveal some absolute truth, but to show that other ways of seeing are also possible. In this way, the given distribution of power is displayed, challenged; its grip is loosened. The method is illustrated in Fowler's *Language in the news* (1991), in his 1979 UEA Inaugural Lecture 'Linguistic criticism' (in Fowler, 1981), in Fowler and Marshall (1985), and discussed in Fowler (1996b), and with respect to power in Fowler (1985). It is revealing that his last book, his study of *The language of George Orwell* (1995), was the one he believed was his best. Like Orwell, Fowler combined a love for and social perspective on literature with a political attack on

linguistic manipulation in "a society of verbal violence – advertising, abuse, rant . . . "

Frajzyngier, Zygmunt (b. 1938)

E Shay, University of Colorado, Boulder, CO, USA

© 2006 Elsevier Ltd. All rights reserved.

Frajzyngier was born April 3, 1938, in Radom, Poland. In 1939 his family fled to the Soviet Union, where Frajzyngier acquired both Russian and Polish as first languages. He later returned to Poland and entered the Institute for Oriental Studies (University of Warsaw), where he studied Ge'ez (Geez; Classical Ethiopian), Amharic, Hausa and Swahili. He earned a Master's degree in Oriental Languages from Warsaw in 1963 and a second Master's, in African Linguistics, from the University of Ghana in 1965. He returned to Warsaw for a Ph.D. (1968) under renowned Ethiopist Stefan Strelcyn; other committee members were Dymitr Olderogge and renowned Indo-Europeanist Jerzy Kurylowicz.

Frajzyngier's first academic appointment was as assistant professor in Semitic and African Languages, University of Warsaw. He lost this job when he applied to the Polish Communist government for permission to emigrate. To obtain an exit visa, he was forced also to give up Polish citizenship. He took refuge in Rome, where he applied to other universities for a position in linguistics. The Linguistics Department at the University of Colorado, then chaired by Luigi Romeo, offered Frajzyngier the professorship he still holds.

Frajzyngier has published more than 100 professional papers and has written or edited more than 15 books. Early publications focused on Hausa and

linguistic manipulation in "a society of verbal violence – advertising, abuse, rant . . . "

Frajzyngier was born April 3, 1938, in Radom, Poland. In 1939 his family fled to the Soviet Union, where Frajzyngier acquired both Russian and Polish as first languages. He later returned to Poland and entered the Institute for Oriental Studies (University of Warsaw), where he studied Ge'ez (Geez; Classical Ethiopian), Amharic, Hausa and Swahili. He earned a Master's degree in Oriental Languages from Warsaw in 1963 and a second Master's, in African Linguistics, from the University of Ghana in 1965. He returned to Warsaw for a Ph.D. (1968) under renowned Ethiopist Stefan Strelcyn; other committee members were Dymitr Olderogge and renowned Indo-Europeanist Jerzy Kurylowicz.

Frajzyngier's first academic appointment was as assistant professor in Semitic and African Languages, University of Warsaw. He lost this job when he applied to the Polish Communist government for permission to emigrate. To obtain an exit visa, he was forced also to give up Polish citizenship. He took refuge in Rome, where he applied to other universities for a position in linguistics. The Linguistics Department at the University of Colorado, then chaired by Luigi Romeo, offered Frajzyngier the professorship he still holds.

Frajzyngier has published more than 100 professional papers and has written or edited more than 15 books. Early publications focused on Hausa and

Awutu (Kwa). The emphasis soon shifted to unresolved questions in Chadic languages and their implications for broader issues in linguistics. Since 1989 Frajzyngier has written complete grammatical descriptions of the Chadic languages Pero, Mupun (Mwaghavul), Lele, Hdi (Xedi) (Frajzyngier and Shay, 2002), Mina (and Eric Johnson, with Adrian Edwards, in press), and Gidar, and has plans for several more. In the 1990s, Frajzyngier developed the Systems Interaction approach, a methodology for analyzing and describing languages without relying on prototype-based or theory-internal assumptions about the nature and existence of linguistic categories and functions. Systems Interaction is based on the Principle of Functional Transparency, which states that every component of an utterance must have a role within the functional categories coded by the language, and the notion of Systems Interaction, the demonstrable functional interrelations among the coding means in the language: lexicon, morphology, syntax, and phonology.

Frajzyngier was a 2002 recipient of the Humboldt Research Award and has held academic appointments at the Research Centre for Linguistic Typology (La Trobe University); the Centre National de la Recherche Scientifique (University of Nice); the Max Planck Institute for Evolutionary Anthropology (Leipzig); and Abdullahi Bayero College (now Abdulahi Bayero University; Kano, Nigeria).

Frame Analysis

C Ruzza, University of Trento, Trento, Italy

© 2006 Elsevier Ltd. All rights reserved.

Through a systematic examination of texts, the methodology of frame analysis provides a content analysis of political documents that systematically analyzes their ideational contents and relational aspects. It aims to document features such as exchanges between political actors, their communication strategies, and changes over time. The use of the concepts of 'frame' and 'framing' clearly indicates a lineage with the work of Erving Goffman, who with this term referred to the textual conjunct function of concentrating attention on some aspects while excluding others. This emphasis on inclusion and exclusion mechanisms, on social controversies and the associated actors and processes, is widely utilized in political research – a scan of a database of political journal articles would for instance bring out well over a thousand references in recent years which use the framing metaphor. However, the framing analytical tradition in social movement research is the approach that since the early 1980s has most consistently attempted to systematize this approach. It has steadily grown in relevance as a useful tool for analyzing political texts and has expanded to other fields such as policy analysis, media studies and more generally various subfields in political sociology and political science.

The interest of social movement scholars in framing processes begins with the consideration that in order to achieve successful mobilization a set of cultural processes of definitions of the situation in terms that are conducive to political engagement and activation of a protest repertoire have to occur. In a society that is increasingly dependent on publicly mediated processes of formation, diffusion, and negotiation of cultural contents, the role of debating arenas becomes crucial. This refers to sectoral social and political arenas such as social movements, political parties, workplaces, and churches, but more importantly one has to emphasize the role of the general media as a debating space in which social issues are framed. Framing theorists concentrate on the operating mechanisms of these arenas and examine topics such as the formation of mobilizing ideas, the responses of opponents, and the processes of redefinition that mobilizing ideas undergo under

Awutu (Kwa). The emphasis soon shifted to unresolved questions in Chadic languages and their implications for broader issues in linguistics. It has steadily grown in relevance as a useful tool for analyzing political texts and has expanded to other fields such as policy analysis, media studies and more generally various subfields in political sociology and political science.

The interest of social movement scholars in framing processes begins with the consideration that in order to achieve successful mobilization a set of cultural processes of definitions of the situation in terms that are conducive to political engagement and activation of a protest repertoire have to occur. In a society that is increasingly dependent on publicly mediated processes of formation, diffusion, and negotiation of cultural contents, the role of debating arenas becomes crucial. This refers to sectoral social and political arenas such as social movements, political parties, workplaces, and churches, but more importantly one has to emphasize the role of the general media as a debating space in which social issues are framed. Framing theorists concentrate on the operating mechanisms of these arenas and examine topics such as the formation of mobilizing ideas, the responses of opponents, and the processes of redefinition that mobilizing ideas undergo under

the influence of movement allies and institutional environments. The concept of frame refers, then, to a central organizing idea that defines for an audience what is important in a debate. Frames also generally specify the causes of a problematic situation and indicate solutions, and movement frames stress the importance of active individual engagement. They often also posit the existence of an injustice that needs to be remedied. Concepts frequently employed in this context are that of the 'master frame,' which refers to a global frame encompassing an entire cycle of protest, and of 'frame packages,' which refers to sets of ideas related to a movement frame but more limited and less stable over time, embodying the discursive strategic activities of organizational leaders dynamically reacting to social controversies.

The production of social meaning, and specifically the production of ideological and policy alternatives to tackle contested social issues, is seen as a process in which a set of actors engage strategically in a societal contest, arguing their points and redefining their position in response to changing events. Social movements face problems of access to debating arenas, problems of formation, unification, and mobilization of consensus within their ranks, and problems of presentation of their perspectives to outside audiences. Their goal is the formation of concerted alternatives to dominant positions on contested issues; that is, the formation of collective action frames. In addition, to achieve widespread social relevance, they have to align their message to aspects of the dominant perspectives, which are known by the public and approved by social institutions. These goals and the methods movements adopt to achieve them were discussed in some key articles by David Snow and Robert Benford in the mid- and late 1980s (Snow *et al.*, 1986; Snow and Benford, 1988). Also influential for this perspective was the early work on the media of William Gamson and his collaborators and the work of Bert Klandermans on the mechanisms that mediate the transformation of a sympathetic attitude towards movements' perspectives into a willingness to engage in political struggle. Klandermans also focused on the difference between unplanned emergence of discourse, which joins the views of relevant social actors, and the planned and strategically orientated formation and diffusion of perspectives, intended to facilitate movements' goals (Klandermans, 1984; Gamson and Modigliani, 1988; Klandermans, 1988; Gamson and Wolfsfeld, 1993).

Whilst there is obviously diversity within this tradition on how exactly to define frames and their mechanisms of operation, and on the important issues to be put on the research agenda, there is sufficient consensus on reasserting the role of culture and communication in social movement research, on stressing social-psychological and cognitive elements in the genesis of social movements and their impact, and in rejecting more comprehensive conceptions of ideology in favor of an approach more conducive to an empirical treatment – a tendency that has recently been criticized (Oliver and Johnston, 2000).

A central assumption of this literature is that social movements do not merely passively present their ideas to the public and their own activists. They are engaged in processes of cultural construction of grievances, and in shaping public opinion, which are in turn influential on participant mobilization. This approach, which stresses the cognitive aspect of frame formation, was innovative when it emerged in social movement theory. The then dominant approaches to the study of social movements – the resource mobilization approach and the new social movements approach – either had little consideration for cultural factors or did not study them systematically, and did not have a methodology to specifically look at the impact of the media. Resource mobilization scholars had argued that grievances are pervasive in modern society. The analytical focus was on how they are adopted by social movements, and on the influential role attributed to political entrepreneurs in gathering and using resources. Conversely, new social movements scholars had related the emergence of social movements to the influence of specific grievances that are linked to various social, economic, and cultural changes, such as the generalized emergence of 'postindustrial' values. Neither of these approaches focused on the 'constructed' character of grievances. An alternative approach, which frame analysts have adopted, was to consider grievances as cultural constructs, and to examine the process of the emergence and construction of issues. As Gamson (1988: 219) noted, this process is highly controversial. Thus, collective action is first of all a search for a definition of the situation. Gamson notes that "for every challenge there is a relevant discourse, particular sets of ideas and symbols that are used in the process of constructing meanings relevant to the struggle." (Gamson, 1998: 223).

At the core of each definition there is a central organizing idea, or frame. To achieve generalized support, movements have to rearrange conventional prevailing frames on the topics of contention and stimulate a new consensus on the necessity of certain policy changes and the appropriateness of mobilization. For instance, in the study of the relation between movements and media Gamson and Wolfsfeld (1993)

showed the power and dependency aspects of the relationship and at the same time the subtle contest over meaning that permeates the interaction between the two parties.

The modification of frames that movements undergo, either intentionally or as a result of broader cultural processes, has been described in terms of the concept of 'frame alignment.' This refers to mechanisms that connect a social movement frame to another societal frame. This connection can take the form of 'frame bridging' when two previously unconnected frames come to be discursively connected. 'Frame amplification' takes place when existing but underspecified frames are articulated and the favorable implications for a movement are emphasized. 'Frame extension' takes place when movements attempt to modify a frame in a direction that is congruent with their views and 'frame transformation' when only a radical realignment of messages can connect a movement frame with public opinion. Through these categories it is possible to accomplish a set of theoretical objectives such as the integration of micro and macro variables and of cultural and structural variables. For instance, Zuo Jiping and Robert D. Benford connect broad cultural patterns to mobilization dynamics (Zuo and Benford, 1995). In their examination of the 1989 Chinese prodemocracy movement they focused on the relation between the ideas prevalent in the population and the attempt by movement activists to present their goals as congruent with these ideas. With reference to activists' discourse, they note:

> Their frame alignment strategies and non-violent direct action tactics tended to resonate with ordinary people's observations and experiences as well as with traditional Chinese narratives of Confucianism, nationalism, and communism. State reactions and counter-framings, on the other hand, failed to sway the masses.

They then proceed to show that framing strategies were related to, though only a part of, a wider set of structural strategies that included the mobilization of preexisting student networks, the impact of economic reforms, regime crises, delayed repression, and the presence of foreign journalists.

In studying the relationship between framing processes and public opinion, special attention has been devoted to the role of the media. For instance, Gamson in *Talking Politics* examined the role of the media in shaping perceptions of certain key social controversies and in the same context investigated the role of social movements (Gamson, 1992).

Whilst much work on frame analysis such as this one has focused on the relationship between movement framing activities and public opinion, studies of the relationship between the themes stressed by movements and specific institutional environments have also appeared. This is particularly the case with policy environments, initially studied by Donald Schön and Martin Rain, who pointed to the socially constructed character of policy making – the fact that policy solutions emerge out of deliberative practices in which actors pursue their goals strategically utilizing the same mechanisms illustrated by social movement researchers (Schön and Rein, 1994). Policy specialists have pointed to the role of paradigmatic crises in specific policy sectors that often spur a global rethinking and the utilization of the radical remedies advocated by social movements. For instance, in this perspective, Carlo Ruzza has studied the diffusion in European Union conventional political environments of the policy frames of a set of movements (Ruzza, 2004).

In terms of methodology, this approach includes informed discussions of methodological aspects (Donati, 1992) and ranges from the most frequent qualitative analyses using excerpts to support the researchers' arguments, to quantitative content analysis, such as in Gamson (1992), and quantitative approaches applied at the micro level (Johnston, 1995).

Recent assessments of this research tradition by some of its original proponents have documented its versatility and some of its substantive outcomes for both descriptive and analytical purposes and have also provided a frank discussion of the main criticisms it has received (Benford, 1997; Benford and Snow, 2000). Among the criticisms one has to list a neglect of systematic empirical studies – researchers prefer to engage in conceptual development – and reliance on limited case studies. There is also a descriptive bias in much of the work on framing which typically seeks to describe types of frames, such as injustice frames, arms control frames, or environmental justice frames, but does not lend itself to new analytical findings. Furthermore, the dynamic element of framing processes is often ignored in favor of a static description of frames that does not take into account their changing nature over time.

Frame Problem

C Viger, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Origins of the Problem

The frame problem, first explicitly identified by John McCarthy and Patrick Hayes (1969), arises in the attempt to design artificially intelligent machines. Intelligent reasoning includes temporal reasoning, such as planning actions or explaining a causal sequence of events. Correct temporal reasoning requires knowing the effects that actions will have in the situations in which they are performed, both the changes and the nonchanges. The frame problem, in its original formulation, is the problem for designers of artificially intelligent systems of how to represent nonchanges, such as when a cup is moved yet its color does not change. For humans such inferences are trivial, just common sense. However, designing systems with common sense has proved to be an extremely difficult problem for artificial intelligence (AI) researchers, making the frame problem of much wider interest than a technical design problem, as it touches on age-old philosophical questions about understanding intelligence – not least as it is manifest in human conversation. In the hands of philosophers, the frame problem has come to refer to a cluster of issues concerning the relevance of the content and speed of human thinking.

McCarthy and Hayes were working within the tradition of using formal logic to design intelligent systems. To handle temporal reasoning, McCarthy had developed the situation calculus, an instance of first-order predicate logic. The formalism indexes time discretely. It includes rules that allow a system to deduce the results of an action, given a description of some situation, i.e., it can produce a description of the situation that results from the action. They applied the formalism to very simple 'toy worlds,' such as a block world consisting of only a small number of blocks on a table and a few simple actions, such as moving or stacking, that could be performed on the blocks. What McCarthy and Hayes realized was that the rules specifying the explicit effects of some action were not sufficient for the system to completely describe the situation resulting from that action. For example, if in situation S1, block A is on block B, and blocks C and D are on the table, the formalism does not allow the system to deduce that in S2, the situation resulting from moving block C onto block D, block A remains on block B. An additional rule specifying that block A remains on block B when block C is moved is required for that inference. The rules specifying the nonchanges during an action are

Frame Problem

C Viger, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Origins of the Problem

The frame problem, first explicitly identified by John McCarthy and Patrick Hayes (1969), arises in the attempt to design artificially intelligent machines. Intelligent reasoning includes temporal reasoning, such as planning actions or explaining a causal sequence of events. Correct temporal reasoning requires knowing the effects that actions will have in the situations in which they are performed, both the changes and the nonchanges. The frame problem, in its original formulation, is the problem for designers of artificially intelligent systems of how to represent nonchanges, such as when a cup is moved yet its color does not change. For humans such inferences are trivial, just common sense. However, designing systems with common sense has proved to be an extremely difficult problem for artificial intelligence (AI) researchers, making the frame problem of much wider interest than a technical design problem, as it touches on age-old philosophical questions about understanding intelligence – not least as it is manifest in human conversation. In the hands of philosophers, the frame problem has come to refer to a cluster of issues concerning the relevance of the content and speed of human thinking.

McCarthy and Hayes were working within the tradition of using formal logic to design intelligent systems. To handle temporal reasoning, McCarthy had developed the situation calculus, an instance of first-order predicate logic. The formalism indexes time discretely. It includes rules that allow a system to deduce the results of an action, given a description of some situation, i.e., it can produce a description of the situation that results from the action. They applied the formalism to very simple 'toy worlds,' such as a block world consisting of only a small number of blocks on a table and a few simple actions, such as moving or stacking, that could be performed on the blocks. What McCarthy and Hayes realized was that the rules specifying the explicit effects of some action were not sufficient for the system to completely describe the situation resulting from that action. For example, if in situation S1, block A is on block B, and blocks C and D are on the table, the formalism does not allow the system to deduce that in S2, the situation resulting from moving block C onto block D, block A remains on block B. An additional rule specifying that block A remains on block B when block C is moved is required for that inference. The rules specifying the nonchanges during an action are

called frame axioms, because they specify the stable frame of reference in which the action occurs.

Frame Axioms Result in Computational Overload

The difficulty with using frame axioms is not that the correct inferences cannot be drawn; it is, rather, that a very large number of frame axioms are required even in simple worlds. For example, adding a painting action to the block world requires distinct rules specifying that each block remains the same color when any block is moved or stacked or when any other block is painted. As worlds become more complex, the number of frame axioms comes to overwhelm the system. Most of the system's computations are irrelevant deductions about what has not changed, making the system very slow and thus unable to function in real time. Also, the formalism is very brittle. Most frame axioms will be false in at least some situations when concurrent actions are possible, leading to false conclusions of the sort that humans rarely endorse. Given the complexity of our environment, it is extremely implausible that we reason using frame axioms. Thus, insofar as it is a goal of AI research to help us understand intelligent behavior, the use of frame axioms is unsatisfactory. The problem, then, is how to represent nonchanges without using a large number of frame axioms.

The Sleeping Dog Strategy and Nonmonotonic Logics

A main strategy for solving the frame problem within AI is called the sleeping dog strategy. The idea is 'to let sleeping dogs lie,' which in the context of the frame problem is to make the assumption that things remain just as they are when an action is performed unless there is some explicit indication of a change. This method uses databases containing statements describing situations. When an action is performed, its effects are computed. Statements that cease to hold are deleted, and statements describing changes are added. All other statements correspond to the nonchanges, so they are included in the database for the resulting situation; the nonchanges are stored in memory, rather than computed.

A difficulty for using the sleeping dog strategy as a solution to the frame problem is that there are often exceptional effects of actions. For example, moving a block does not ordinarily change its color, but it does in the exceptional case that the block is moved under a spray painter. Intuitively, what is required to handle exceptional cases is the ability to draw a new conclusion upon learning new information. Formally what is required is that by adding a premise, the deduction of one conclusion can be transformed into the deduction of a different, contradictory conclusion such that the original conclusion no longer follows – on pain of inconsistency. The difficulty is that classical logics do not have this property. They are monotonic, which is to say that any conclusion that follows from a set of premises also follows if further premises are added. In response, AI researchers have developed a number of nonmonotonic logics in which adding new premises blocks the derivation of the original conclusion. Using nonmonotonic logics makes it possible to derive new, contradictory conclusions when exceptional circumstances formalized as additional premises are added to a derivation. This often involves adding a premise indicating that the action is abnormal in the given situation, so that the usual conclusion ceases to follow.

The Yale Shooting Problem

Even when nonmonotonic logics are used, there are still problems in trying to use the sleeping dog strategy. The most famous such problem is known as the Yale Shooting Problem, introduced by Hanks and McDermott (1986). The scenario in the Yale Shooting Problem is that a gun is loaded at some time t. For a number of discrete time units following t, the action taken is to wait. Then the gun is fired at Fred. The intuitively correct outcome is that in the next time unit, Fred is dead. The formalism predicts this by taking the gun's being loaded as the sleeping dog that persists. Though being alive is a state that usually persists, being shot by a loaded gun is abnormal with respect to being alive, so Fred must be dead. The formalism also predicts that Fred is alive, however, by treating the state of being alive as the sleeping dog. The reasoning in this case is that since Fred is alive, the gun must have become unloaded during the waiting, treating the action of waiting as being abnormal with respect to the gun's being loaded. The formalism cannot determine which sleeping dog, Fred's being alive or the gun's remaining loaded, should be left to rest in the given situation, so it cannot predict whether Fred is alive or dead. The problem comes about because in nonmonotonic logics the addition of a premise – the gun is shot – can undermine support for some conclusion. When more than one conclusion can become unsupported – Fred is alive, the gun is loaded – the formalism has no way to decide which one to keep, leading to contradictory predictions about the new situation. In some cases the conflict is a virtue, because it models our own uncertainty of the

outcome, but even when the outcome is obvious to us, the formalism is stymied.

Holism Presents a Problem for the Sleeping Dog Strategy

A more general philosophical concern with the sleeping dog strategy results from the holistic nature of commonsense inferences. In the right situation, virtually anything we know might be relevant for successfully predicting the outcome of an action. A dropped paper clip will fall to the ground, unless it is in a magnet field. My love of pizza could even affect the New York Stock Exchange if I order the last slice of pepperoni ahead of a multibillionaire who then invests irrationally after lunch. There is no principled way that anyone yet knows of for determining which sleeping dogs need to be woken in a particular situation. (This reading of the frame problem as a problem of accessing relevant information is of interest to linguists and philosophers of language attempting to understand what is said in making an utterance over and above its literal meaning. Research here is being conducted at the interface of pragmatics and semantics.)

AI researchers such as McDermott (1987) and Hayes (1987) criticized the broad philosophical interpretation on the grounds that it is not the real frame problem. Instead, philosophers are focused on problems of relevance and prediction, which are related to, but distinct from, the frame problem. Distinguishing these problems is more than mere pedantry; it stems from a general optimism that progress is possible following a divide-and-conquer strategy that is often successful in science. Clear distinctions also further understanding. Philosophers such as Fodor (1987, 2000) are much more pessimistic, since they see the problem as generalizing. Defining the frame problem so narrowly that it is solvable leaves the much wider problem of relevance untouched. Insofar as it is the aim of AI research to design intelligent machines, progress will be impeded until holistic reasoning can be modeled. For example, abductive reasoning, such as judging which of two hypotheses is simpler, faces the same problem of computational overload that we see in the traditional frame problem, and for the same reason, according to Fodor (2000). Whether or not some hypothesis is simple depends on the theory and background assumptions into which it is embedded. As a result, computing simplicity seems to require computing over an entire theory; yet we make simplicity judgments in real time, leaving us with the problem as to how a computational model can account for abductive inferences.

Concluding Remarks

Since the formulation of the frame problem, attempts to solve it have led to many advancements in logic and computer science that are significant in their own right, much as work on Fermat's last theorem developed mathematics. Though researchers do not agree on just what the problem is or the progress that has been made, most agree that progress on the frame problem is central to the development of cognitive science.

Frame Semantics

C J Fillmore, University of California at Berkeley, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Frame semantics is first of all an approach to describing the meanings of independent linguistic entities (words, lexicalized phrases, and a number of special grammatical constructions) by appealing to the kinds of conceptual structures that underlie their meanings and that motivate their use. These conceptual structures, called frames, can be schematizations of particular situation types and their components such as the events or states expressed by simple verbs or adjectives, e.g., *lift* or *similar*; large-scale institutional scenarios such as commercial transactions or judicial process; patterns of contrast such as that between winning and losing; networks of relationships such as what is found in kinship terminology; and a great many others. The words or other linguistic entities in a text or discourse **evoke** or **project** their frames in the minds of the language user and figure in the cognitive process of language interpretation.

In 1983, Victor Raskin convened a Congress Workshop at the 13th International Congress of Linguists in Tokyo under the title 'Round Table Discussion on Frame/Script Semantics.' A 1985 volume of papers (Raskin, 1985), including many from researchers who did not participate in the Tokyo Round Table, became the first general collection on this broad topic, characterized mostly as work that accepted cognitive structures with names such as *frame*, *schema*, *script*, and *scenario*, that led one away from prevailing views of semantics within the Katz and Fodor (1963) tradition in generative grammar. In 2003, at the 17th Congress of the same organization, in Prague, a second Frame Semantics workshop was held, and the range of approaches was again quite broad. Collections of papers from that workshop are said to be forthcoming.

The kinds of phenomena dealt with in frame-semantic analysis can be illustrated with a few examples.

Oppositions

If we read of kestrels that they 'sometimes nest *on the ground*,' our picture of kestrel nesting behavior has us imagining that these birds otherwise build their nests in trees, or perhaps under the eaves of buildings or in bird houses. But if we read of auks that they 'build their nests *on land*,' this matches or perhaps induces our understanding that these birds otherwise spend most or all of their time in or above water. This is because there are conventional pairings between the words *ground* and *air*, as between *land* and *sea*, matched by phrasal contrasts between *on the ground* and *in the air* on the one hand, or *on land* and *at sea* on the other hand. Each member of such contrast sets evokes an understanding of the contrast as a whole.

We hear that someone named Jim "spent two hours *on land* today," and we conclude easily that this is an interruption of a sea voyage; or we hear that he "spent two hours *on the ground* today," and we see it as an interruption of a period of air travel. There is yet another such contrast, using the word *earth*, as can be recognized in the report that Jim "spent only a few years *on this earth*": we assume this time that we are being told that he is now in heaven – or possibly that he has returned to outer space.

It is important to realize that these conclusions are based, not on **information** about where these nests or people are located, but on the **words** used to express that information, words that evoke the frames against which the fuller understanding is structured. We could, in fact, have a single snapshot image of Jim doing something somewhere on the earth's surface that fits any of the three framings.

Word Choice

Sometimes we are surprised by the use of a word in a particular context, and inquiry leads to an explanation involving the 'framing' role of words. If we were to buy some herbal medicine at an American health-food store and wished to find out how much we should ingest in order to treat our problem, we might be surprised to read on the product label that one *serving* is two capsules. We expect the language on the package to match our framing of the product as a medicine, but the word *serving* surprises us. We would have expected something like *dose* or *dosage*.

Officially, the product we bought is neither a food nor a medicine: it is a dietary supplement, more or less limited to botanics, vitamins and minerals. The U.S. Food and Drug Administration has premarketing regulatory authority over food and medicine, but it has only postmarketing monitoring authority over dietary supplements. This means that if any such product is described on labels or packaging as effective for specific medical conditions, or is directly or indirectly presented to customers as a medicine, it can be taken off the market. Since the words *dose* and *dosage* would surely evoke the medicine frame, marketers of dietary supplements refrain from using it. It is not, strictly speaking, a food either, but the term *serving*, while seeming out of place, is presumably safer.

Beyond Literal Meaning

It is common to believe that a sentence can have a *literal meaning*, namely that part of the meaning that determines its truth conditions, and that the more elaborated in-context meaning is attained by fitting that literal meaning into an awareness of the context of communication and assumed answers to questions about why it was said, when it was said, and the like. Presumably in the literal meaning of

Reviewers praised the cellist.

any truthful utterance of the sentence has to refer to a group of people who happen to be reviewers, and a person who happens to be the in-context designated cellist. If the people identified as reviewers said something positive about the person called the cellist, then the sentence is literally true, even if they met in a bar and what they said was something like *Nice haircut!* That same literal meaning would have been achieved (on this narrow view) if the reviewers had been identified by a list of names and if the cellist had been identified by a pronoun.

We need more than context and literal meaning to explain the most natural out-of-context interpretation of that sentence, however, since the words themselves evoke situations whose details need to get filled in in the cognitively most straightforward way. The meaning of *reviewer* that makes most sense in this context is a person who writes reviews of artistic performances; the *praising* in this case would be understood as expressed in the text of such reviews; and the *cellist* would have been praised for his or her performance on a cello as part of the event about which the reviews were written.

In all of the above examples, it seems clear that what is needed for understanding the meanings of particular linguistic signs is a two-fold structure, separating an institutional or experiential background from what is profiled or foregrounded within that background. That is, we need both the words and the frames.

Frames and Framing

Two separate traditions, one inside linguistics and one outside, have come together in motivating both the activity referred to as frame semantics (FS) and, coincidentally, the use of the word *frame* within that activity. In the examples just examined, the word 'frame' has been used very broadly, but we see in each case that the frame that participates in the interpretation is associated with a particular lexical or grammatical fact. Since frame semanticists are frequently asked about the relationships between different uses of the same term of art, some clarification seems appropriate.

Cognitive Frames

There is a common nonlinguistic use of this word where it refers not to what a piece of language evokes in the mind of an interpreter, but what kinds of conceptual structures an interpreter invokes to make sense of some experience.

This nonlinguistic use of the concept has a long history (Bartlett, 1932; Piaget, 1971; Mill, 1846; see Fillmore, 1985), but it flourished in the cognitive and social sciences in the 1970s. The idea behind this work is that people understand what they are observing by calling on memories of past experiences, or by construing what is observed as instances of or variations from structures of belief and experience that could be used to make sense of what they have heard or observed. These structures in the mind are called frames, and these are not necessarily connected in specific ways with language (*see* **Frame Analysis**).

Minsky Frames To Marvin Minsky (1981, 1985), the mind is equipped with a vast repertory of such ready-made (i.e., from past experiences) frames, and people are capable of bringing these to bear, with

remarkable ease and speed, to make sense of their perceptual and other everyday experiences, such as recognizing familiar objects on limited visual evidence, or assigning one or another interpretation to ambiguous line figures.

A well-known example of Minsky's that involves a response to language centers around the Birthday Party frame. Consider what's involved in making sense of the following two-sentence text,

> *Mary was invited to Jack's party. She wondered if he would like a kite.*

There is nothing in the text that directly evokes the idea of a birthday party, but a typical interpreter quickly and easily invokes just that frame in order to make the text cohere. The kind of event that fits a child's birthday party frame in this culture contains 'slots' for certain expected participants, props, and subevents. We expect such an event to have a celebrant, a host, a number of partygoers, and gifts, and other items such as balloons, cakes, candles, and the birthday song. The interpreter makes the parts of the text cohere by the cognitive process of filling in as many of the slots as possible on the basis of what he has just learned – here with Mary as a partygoer, Jack as the celebrant, and the kite as Mary's potential gift for Jack – and populates the other slots with default values that characterize the typical child's birthday party. (World knowledge invited us to assume that this is a child's birthday party, but if the potential gift had been identified as a box of cigars rather than a kite, that would have been different.)

Again, there is nothing in the text itself that invites the Birthday Party frame: that is the interpreter's contribution. The language conveys certain information, without directly providing the framework, and the interpreter makes it cohere.

Goffman Frames Important in the work of Erving Goffman (1974) is the notion of mistaken framings and their possible consequences. Take a variant of a Goffman example: an instance of roughhousing on the street between young boys could be construed by an outside observer as either Combat or Play. An adult observer might 'misframe' a playing event as combat, and believing that the person who has the upper hand is likely to do serious harm to his coparticipant, might inappropriately intervene – and might discover his mistake when both boys attack him.

Frame semantics, in contrast, is concerned with how situation types are evoked specifically by linguistic entities: if Minsky's example had included either of the phrases *birthday party*, *birthday cake* or *birthday present*, that could have evoked the frame; if the boys in the Goffman example had declared, "We're just *playing*, Mister," that would have provided a linguistic encoding of the frame, i.e., would have instructed the observer on the proper frame to invoke (*see* **Goffman, Erving (1922–1982)**).

The Word 'Frame' in Linguistics

The nonlinguistic strand, which has figured in sociology, cognitive science (including artificial intelligence and cognitive psychology), and theories of narrative, and has used the words 'frame' and 'schema' in essentially the same way, has to do with the structures of knowledge that enabled people to interpret (or misinterpret) the things they experienced.

Frame semantics in its current form was influenced by this nonlinguistic strand, but also arose as part of a continued exploration of what was called case grammar (Fillmore, 1968, 1977). Within this linguistic strand, in its earliest history, the word 'frame' had nothing to do with cognitive acts of construal, but instead organized fairly mundane matters of grammar and semantics. 'Syntactic frames' were proposed as slot-defining contexts that provided criteria for membership in particular word classes. For example, the frame [the very ___ thing] could represent a context for prenominal adjectives. In generative grammar (Chomsky, 1965), 'subcategorization frames' defined slots for the various kinds of English verbs, i.e., according to whether they required direct or prepositional objects, directional or manner adverbs, etc. This narrowly syntactic sense of 'frame' was expanded in case grammar.

Case Frames In the early work of Charles Fillmore and his colleagues (Fillmore, 1968, 1978), the term 'case frame' was introduced to describe the semantic 'valence' of verbs (mostly). Early treatments of valence, tabulating the combinatory properties of predicating words, were more or less limited to (1) specifying the number of arguments a verb could take (intransitive verbs take one argument, transitive verbs take two arguments, a smaller class of verbs take three or more arguments), and (2) specifying information about the grammatical requirements on the dependents that a predicating word could 'take' – in traditional Latin grammars, this could include the grammatical cases (nominative, accusative, dative, etc.) of accompanying nominals and the ways in which prepositional phrases could introduce less central meanings. Discussion of the semantic aspects of verb valence was more or less limited to information about very general semantic properties of argument nominals (human, inanimate, abstract, etc.), summary descriptions of the uses of the cases and

prepositions (as in traditional Latin grammars), and classifications of the kinds of verbs that were likely to occur in one or another of these patterns.

Fillmore's (1968) proposal was that the 'semantic valence' of a verb could be identified independently of the manner of grammatical realization of the verb's arguments, in terms of semantic role notions (called deep cases) that classified such participant types as the perpetrator of an action (Agent), an entity that moves or is capable of moving (Theme), the destination of a movement (Goal), the starting point of a movement (Source), and several others. A combination of deep cases that together expressed the semantic part of a verb's combinatorial requirements was referred to as its case frame.

The sets of deep cases that could occur with verbs of one sort of meaning (e.g., Placing) could frequently be seen as characterizing all of the verbs with similar meanings (*set*, *place*, *put*, *stand*, *insert*). The case frames therefore naturally came to be thought of as characterizing particular event types, and this classification could be importantly different from classifications based on grammatical context differences. Thus the combination {Agent, Theme, Goal} could serve as role names for the participants in Placing events, independently of how the these participants were actually expressed in the grammar of a sentence.

Case grammar was designed to show both how the various cases combined to classify verbs and other predicates, and how the grammar of the language allowed these to be matched with surface grammatical structures. However, it eventually became possible to think of these classifications – these frames – as the primary concepts, identifying situation types on their own, and the semantic role names as identifying the participants in such situations – somewhat analogously to the gift, cake, and celebrant in a birthday party, with the difference that case frames were tied to the grammar of particular lexical items.

The case frames started out as clusters of participant roles using, initially, names from an assumed universally valid finite inventory of such roles and it was thought that any verbal meaning could be seen as using some collection of these. The frames of current frame semantics, in contrast, are described in terms of characteristics of the situation types themselves, including whatever could be said about the background and other associations of such situations. Moreover, the goal of limiting the number of semantic roles to a roster of reusable universal role names lost its importance, and the effort to force any frame-specific semantic role into the members of such a list could be abandoned in good conscience.

Merging the Two Research Strands

In merging these two strands of talk about frames, a frame semantics that goes beyond verb valence now includes within its scope fairly large and multilayered structures, like baseball or commerce or movie production, which incorporate complex connected patterns of knowledge and terminology.

Frame semantics continues to be closely tied to linguistic form, but in recent work (i.e., in FrameNet; see 'Frames and Lexicon' below) it has proved useful to distinguish 'small frames' associated with individual predicates from 'big frames,' i.e., the institutional concepts that were themselves identifiable by names (birthday, but also commerce, computation, criminal process, etc.). In the current framework, the differently motivated needs for a frame concept unite. This joining supports semantic analysis that accommodates the richness of the cognitive work that goes into linguistic interpretation and expression. It also allows us to investigate more precisely and powerfully the linkages between grammar, lexicon, and the contents of experience.

Frames and the Lexicon

Sponsored by the National Science Foundation and housed at the International Computer Science Institute in Berkeley, California, the FrameNet project is building a frame-based lexicon for English; in collaboration with researchers in Europe and Asia, the extent to which semantically valid lexica can be built for other languages using the same principles is being investigated. The project takes a lexicon to be a vast inventory of the words, multiword phrases, and grammatical constructions that speakers of a language have to know outright, as contrasted with those abilities speakers have for generating or interpreting language by building on the things they already know. A frame-based lexicon associates each lexical unit that it evokes, together with the patterns by which the grammar of the language provides information about the frame in words and phrases which are in construction with the LU.

The ongoing work of the FrameNet project (Fontenelle, 2003) differs from that of ordinary lexicography in an important way: instead of working with a single word and exploring all of its meanings, it takes a single frame and examines all of the LUs that evoke that frame. In practice, of course, such work begins by considering a word in one of its senses and exploring the frame that goes with just that sense. To illustrate, the verb *cure* in its medical care sense

(as in to *cure a disease*) is one LU; the same verb in its food preservation sense (as in to *cure ham*) is another LU and calls for a separate frame. Instead of depending on dictionaries or native-speaker intuition to summarize what can be known about the LU, FrameNet, taking advantage of the power of computers, the easy availability of vast text resources and tools for managing and manipulating these, bases its findings on corpus evidence. Currently our corpus base includes one hundred million running words in the British National Corpus plus two hundred million words of U.S. newswire text.

FrameNet entries are built up in the following way. A group of LUs is chosen as representative of a single frame; taking one LU at a time; example sentences containing it are extracted from the corpus and sorted by syntactic context; representative samples are selected that clearly illustrate the sense in question; and the selected sentences are annotated according to the frame the LU evokes. Before the annotation begins, labels are chosen to represent the semantic roles or frame elements (FEs) that the LU has in respect to the given frame, for example, Buyer, Seller, Goods, Money, etc., for the various frames connected with Commerce. Sentence constituents that are grammatically linked to the LU in question are assigned appropriate FE labels, and the constituents thus labeled are also provided with information about their grammatical function (GF) – Subject, Object, etc. – and their phrase type (PT), e.g., finite *that*-clause, marked infinitive VP, NP, etc.

Important steps in these processes are carried out automatically and several are computer-assisted, but an indispensable core is handled manually by trained native-speaker annotators who have to read and understand the sentences and make judgments about the fit of each usage with the frame currently being studied.

An Example: The Revenge Frame

The analysis process can be exemplified by considering the Revenge frame. Any situation that can be thought of in terms of a revenge concept has an associated scenario or history. Within that history, one person has done something to offend another person (the FE names for these individuals are the Offender and the Injured Party, respectively, and the offending act is referred to as the Injury), and one person, called the Avenger, who may be but need not be identical to the Injured Party, undertakes to harm the Offender, in response to the Injury, with an avenging act called the Punishment. The roster of core FEs, those FEs that are criterial for the frame, then includes Avenger, Offender, Injured Party, Injury, and Punishment. The project in its current work also annotates peripheral FEs, those that can accompany expressions within the frame, indicating such matters as Time, Place, Manner for events, Purpose, and a few others for events that are also acts, and so on. In general practice, the core FEs are given frame-specific FE names, whereas the peripheral FEs are given 'reusable' names that do not require frame-by-frame definitions.

The words that evoke the Revenge frame include simple verbs such as *avenge*, *revenge*, *retaliate*; phrasal verbs such as *get back*, *get even*; nouns such as *vengeance*, *revenge*, *retaliation*, *retribution*; adjectives that characterize the punishment such as *retaliatory*, *retributive*, *vindictive*; adjectives that describe the intensity of feeling of the person carrying out the revenge such as *vengeful*, *vindictive*; and support verb constructions such as *take revenge*, *wreak vengeance*, and *exact retribution*.

Examples of annotations in the Revenge frame are offered in **Figure 1**.

As can be seen in **Figure 1**, the linking of FEs to their grammatical realization is variable, though the Avenger is uniformly linked to the subject position of an active verb. The Offender is introduced by a variety of prepositions: *on*, *with*, *at*, and *against*, the Injury can be a direct object or an object of the preposition *for*, and so on. Several features not discussed so far are indicated in the annotations. At the end of each sentence there are representations of null instantiation: these notations have symbols such as DNI and INI in place of lexical material, and they indicate that the missing FE is either understood in the context (DNI = definite null instantiation), or are simply unspecified (INI = indefinite null instantiation). The last few sentences are examples of support constructions, where the verbal meaning is expressed by a combination of a support verb and a Revenge noun: *have vengeance* (11), *exact vengeance* (12), *take vengeance* (13), *wreak vengeance* (14), and *visit retribution* (15). The subject arguments are sometimes attributed to a verbal frame if the phrases that express them are arguments of control verbs, as with the subjects of *wish to avenge* (1), *determined to avenge* (2), *proceed to wreak vengeance* (14).

Polysemy

The words in the Revenge frame have mostly a single meaning, but many of the words examined in FrameNet have multiple senses, which almost always means that they belong to different frames. We decide that a word belongs to different frames (i.e., that it formally supports different LUs) on the basis of such criteria as its relationship with other frames, the permitted

1. [^{Avenger}The Trojans] wish to AVENGE^{Target} [^{Injury}the death of Hector]. [^{Offender}DNI] [^{Punishment}INI]
2. [^{Avenger}America's top two golfers] are determined to AVENGE^{Target} [^{Injury}their recent defeat in the Dunhill Cup at St Andrews]. [^{Offender}DNI] [^{Punishment}INI]
3. Ravana captured Hanuman and set fire to his tail, but [^{Avenger}the monkey] AVENGED^{Target} [^{Injured_Party}himself] [^{Punishment}by growing to the size of a giant and setting fire to the city]. [^{Offender}DNI]
4. Oneday [^{Avenger}she] would GET EVEN^{Target} [^{Offender}with Donna] [^{Injury}for this]. [^{Punishment}INI]
5. [^{Avenger}I] 'll GET EVEN^{Target} [^{Offender}with you] [^{Injury}for this]. [^{Punishment}INI]
6. [^{Avenger}The USA] RETALIATED^{Target} [^{Injury}against the harassment of its diplomats] [^{Punishment}by expelling 36 staff from the Iraqi embassy in Washington – including seven accredited diplomats – on Aug. 27, and imposing restrictions on the 19 who remained]. [^{Offender}DNI]
7. [^{Avenger}Groups of Muslim demonstrators] RETALIATED^{Target} [^{Punishment}by attacking the nearby Holiday Inn with small arms and grenades]. [^{Injury}DNI] [^{Offender}DNI]
8. [^{Avenger}Iraq] also RETALIATED^{Target} [^{Punishment}by launching Scud missiles against Saudi Arabia and Israel]. [^{Injury}DNI] [^{Offender}DNI]
9. [^{Avenger}A neighbor] RETALIATED^{Target} [^{Injured_Party}on behalf of his fallen friend]. [^{Offender}DNI] [^{Punishment}INI]
10. Have [^{Avenger}you] come to REVENGE^{Target} [^{Injured_Party}yourself] [^{Offender}on me] [^{Injury}for failing you]? [^{Punishment}INI]
11. My God, [^{Avenger}she] would [have]^{Supp} VENGEANCE^{Target} [^{Injury}for this]! [^{Offender}DNI]
12. [^{Avenger} The Turks] [exacted]^{Supp} a [^{Manner}terrible] VENGEANCE^{Target} [^{Offender}on the helpless Serbs]. [^{Injury}DNI]
13. The old forests burned as [^{Avenger}the Dark Elves] [took]^{Supp} VENGEANCE^{Target} [^{Injury}for their long exile]. [^{Offender}DNI]
14. The king was taken to Renilworth Castle while [^{Avenger}Isabella and Mortimer] proceeded to [wreak]^{Supp} [^{Avenger}their] VENGEANCE^{Target} [^{Offender}on his supporters]. [^{Injury}DNI]
15. One function is to [visit]^{Supp} RETRIBUTION^{Target} [^{Offender}upon people who have broken the law].

Figure 1 Annotations from the Revenge frame.

inferences associated with given FEs, synonyms and antonyms, and the grammatical patterns in which they are expressed. For example, the word *remember* needs to be assigned to different frames as shown in the examples in Table 1. (The use found in *Remember me to your parents* has not been included.)

The FrameNet Database

The FrameNet database has four main components: descriptions of frames and frame elements; the body of annotated sentences; lexical entries that show for each LU the variety of ways in which the FEs are grammatically signaled; and information about how the frames are related to each other.

The Basic Data Proceeding by frames rather than words means that members of a single frame can include words from all major parts of speech. As seen in the annotations in Figure 1, the data collected involves more than verbs and their expressed arguments. Verb-headed and adjectival expressions that make use of the frame-bearing functions of various kinds of nouns occur with the help of support constructions of various kinds. We saw expressions such as *take revenge*, *wreak vengeance*, and *exact retribution* in the Revenge annotations, where the syntactic head and the semantic head are discrepant: to the extent that the verbs make their own semantic contribution, they are made to fit into the frame structure

Table 1 Polysemy of *Remember*

Frame name	**Remembering_experience**
Interpretation	recall of personal experiences, episodic memory
Examples	*I remember as a child falling down the steps in my grandmother's house.*
	I remember something touching me in the dark.
	I remember you as much taller.
Synonyms and paraphrases	*Recall, recollect, have a memory of;* associated with count-noun *memory*
Complement types	VP-gerunds, S-gerunds, NP + Predicate
Relationships	Not paired with *forget* or *know*
Frame name	**Remembering_information**
Interpretation	Keeping knowledge, continuing to know
Examples	*I didn't remember that the meeting was today.*
	Do you remember what she said?
	I hope they remember my phone number.
Complement types	S-that, S-wh, VP-wh, 'concealed question' NP
Relationships	Paired with frames led by *forget* and *know*
Frame name	**Remembering_to_do**
Interpretation	Thinking of some preknown task or intention at the appropriate time
Examples	*Did you remember to feed the cat?*
	I hope she remembered her umbrella.
Complement types	VP-inv, NP with *coerced* verb
Relationships	Paired with *forget*, not with *know*

evoked by the object noun. And nouns can be 'supported' to create adjectival expressions with the help of prepositions, as in *at risk*, *in danger*, *on fire*, and scores of others. The FrameNet database allows the recovery of such information through associated browsing software.

A commitment to account for all frame elements that are conceptually necessary for a given frame-bearing word has required the development of annotations for missing but understood elements, through a variety of indications of null instantiation. The concept **d**efinite null instantiation (DNI) is associated with a given FE in a given sentence as a signal of zero anaphora: some value to the FE thus tagged must be available in the shared context of speaker and hearer, and this is a property associated with particular LUs or the words in particular frames. The destination of verbs of Arriving can be omitted under anaphoric conditions if they would otherwise be expressed prepositionally; the speaker who says *She's arrived!* assumes that the addressee already knows the intended destination. The destination of *reach* cannot be left unexpressed: *She's reached *(home)*.

The Frame-to-Frame Relations FrameNet captures linguistic generalizations in a number of ways. The 'Net' part of the name refers to the frame-to-frame relations in addition to LU membership in individual frames, both of which are potential sources of generalization. The fact that the frame-specific FE Avenger has a preferred subject-linking preference should be represented in some way that recognizes the 'agency' associated with this FE; although there are good reasons for not wishing to be limited to the familiar thematic roles from the linguistic literature, it is nevertheless possible to see a great many verbal frames as instances of more abstract frames of action, change, motion, experience, causation, etc. Providing a systematic display of the full network of *inheritance* relations between frames is an ongoing area of development.

Some frames represent complex events that are made up of component events, and these contained events can have frame structure as well. A structure of 'subframe' relations is created to show the role of Money_transfer in Commerce, the role of Ratifying_treaty in a larger Diplomacy scenario, and so on. In many cases, a subordinate frame presents a perspectivization on the larger frame. For example, a broadly conceived frame of Employment lays out a large set of situations and changes, within which there are perspective-taking frames of Hiring, Employing, Firing, Taking_a_job, Working, Quitting, and several others. A major frame of Criminal_justice_procedures contains components of Arresting, Arraigning, Trying, Adjudicating, and Sentencing, as well as a number of alternate routes through that chain. Relations such as those of inheritance and subframe are needed for deriving inferences from frame-based assertions, and this must include FE-to-FE binding

between lower and higher frames, and transitively between the elements of lower frames where appropriate. The individual who undergoes Arrest and then Arraignment in two successive phases of a complex criminal_procedure scenario is the same as the Defendant in the (later) Trial and Adjudication scenarios, and so on. For a well-designed system to carry out inference on frame-annotated texts, such bindings have to be made formally explicit, and the work to make this possible is under way.

Applications and Extensions

Frame semantics has in a sense two subfields, and these can be thought of as the drudgery part and the fun part. The drudgery, or painstaking foundation part, is the work of actually building a frame-based lexicon and integrating it into a particular kind of grammar of the language. The fun part is that of analyzing how the actual choice of a lexical item evokes a frame, and what follows from that evocation. Here are just two classes of such consequences.

One type of consequence concerns aesthetic and persuasive effects: frame semantics may be able to provide a precise basis for the analysis of the effects stemming from word choice in poetry and prose as well as texts of a more propagandistic sort. Current political discourse in the United States makes a great deal of use of 'reframing' (Lakoff, 2004) in political discourse to associate personal values with the propagandist's political positions: when talk of *tax reductions* is rephrased as *tax relief*, the image of someone who has been suffering is highlighted; when *estate tax* is spoken of as *death tax*, the unwelcome image of being punished for dying comes to the fore; if in the debates about the morality of abortion, a week-old fetus is referred to as *the little baby*, then the association is created of a small and helpless human being needing adult protection (*see* **Politics and Language: Overview**).

Second, there are potentially powerful uses of frame-semantic notions within the fields of Natural Language Processing. As of this writing, several projects are under way to show the relevance of frame-semantic representation in such tasks as automatic sense resolution, semantic tagging, question answering, and machine translation. More far-reaching uses for work in NLP lie ahead (*see* **Natural Language Processing: Overview** and **Machine Translation: Overview**).

France: Language Situation

P Rowlett, University of Salford, Salford, UK

© 2006 Elsevier Ltd. All rights reserved.

Metropolitan France (population 59.9 million) is a liberal constitutional republic in Western Europe and a member of the European Union. While French is used by the vast majority of the population (82% are native speakers), and is the only official language of government and administration, and the dominant language of culture, journalism, and broadcasting, various other languages are used, often in situations of diglossia. Indeed, although the fact has long effectively been ignored, France is one of the most linguistically diverse countries of Europe, even though the 75 languages catalogued by Cerquiglini (Cerquiglini, 1999) include those spoken in French overseas departments and territories, and the vast majority of the 400 identified by the national institute of statistics (INSEE) (INSEE, 2002) have very small numbers of isolated speakers.

The other languages of France are both regional heritage languages (*les langues régionales*), with histories at least as long as that of French, and the more recently introduced migrant languages (*les langues immigrées*). French itself developed out of Francien, one of a number of varieties jointly labeled Langue d'Oïl and historically spoken across the northern two-thirds of the country. A few other Langue d'Oïl varieties (Poitevin-Saintongeais, Gallo, Normand, Picard, Champenois, and Morvandiau) survive away from the Île-de-France. In the extreme West, two major dialects of Breton, France's only remaining Celtic language, are spoken by 240 000–370 000 of a population of 1.5 million. Near the western Belgian border in the north, 20 000–40 000 people in Westhoek (pop. 300 000) around Dunkirk in an area covering one quarter of a single department (Nord) have some knowledge of West Flemish, France's smallest regional heritage language. In the northeastern Alsace-Lorraine, Alsatian has about 1 million speakers, approximately half the population of Alsace, while Lorrain (or Moselle Franconian) has 78 000 speakers. In a fairly large triangle in the east are spoken a number of varieties of Francoprovençal, a diffuse transition area between the Langue d'Oïl and southern Langue d'Oc area. Estimates of the number of speakers are in the order of 1% of the population, that is, about 60 000. On the Mediterranean island of Corsica (apart from the town of Bonifacio, where 300 to 400 people speak Ligurian), a number of local varieties of the Italo-Romance Tuscan, known together as Corsican, are spoken by less than half of the 280 000-strong population, and understood by probably a further 20%. Corsican is unique among France's regional heritage languages in having a legal status, which is linked to recent political/administrative devolution on the island. Extending across most of the southern third of France, speakers of half a dozen mutually comprehensible varieties of Occitan number 2 million to 3 million. At the eastern end of the Pyrenees, about 126 000 people in Pyrénées-Orientales (pop. 370 000) speak Catalan. At the western end of the Pyrenees, three varieties (Labourdin, Low Navarrese, and Souletin) of Basque, Europe's oldest and France's only non-Indo-European regional heritage language, are spoken by some 40 000 people in the Pays Basque Nord (pop. 260 000), and understood by perhaps a further 12 000.

Of the increasingly diverse (that is, non-European) foreign and migrant population, the largest groups are from France's former North African colonies and speak Maghrebian Arabic (1.37 million) and Kabyle or Tamazight Berber (687 000). Then comes Italian (1 million speakers), Spanish (260 000), Portuguese (150 000), French Creole (from Réunion, Martinique, Guadeloupe, and Guyana) (150 000), Turkish (135 000), Western Armenian (70 000), Farsi (40 000), Khmer (50 000), Wolof (35 000) and Vietnamese (10 000). Fewer numbers of people speak Yiddish and Romani.

The future health of these minority languages varies widely, but is generally questionable. The relevant factor, however, is not absolute number of current speakers, alone, although it is true that Breton and Flemish are spoken in increasingly shrinking peripheral areas. More significant is speaker profile and language competence, itself related to strength of sense of united community and cultural identity. There are no longer any monolingual speakers of regional heritage languages, and their use is increasingly the reserve of older generations in lower socioeconomic groups in rural areas. Thus, while these low-prestige varieties continue to be spoken among adults, they are not passed on to younger generations, who see little practical value in them. The most robust regional heritage languages, in relative terms, include Alsatian, Basque, Catalan, and Corsican. But even in Alsace-Lorraine, only between one-half and one-third of children under 15 speak Alsatian and Lorrain, despite the fact that in 1994 two-thirds of Alsatians were in favor of bilingual education from primary school upward. With both Catalan and Basque, the lifeblood is in Spain (for example, about 90% of Catalan speakers live in Spain, with better age profile and transmission rates), and the communities in

France are very much of secondary importance. Particularly vulnerable are the varieties of Langue d'Oïl, Francoprovençal, Breton, Flemish, and Occitan. Francoprovençal has much dialectal variation and no unifying popular identity, literature, or urban center; it is moribund in France (and in neighboring Switzerland, too, although it is apparently holding up better in the Val d'Aosta, Italy). While some regional heritage languages have large numbers of speakers, it is the migrant languages that, in terms of age profile and language competence of current speakers, as well as transmission rates to younger generations, are doing best. INSEE surveyed the all-important early-childhood linguistic behavior among a sample of 380 000 people (0.63% of the metropolitan population). It showed that French is making steady progress, but at the expense of regional heritage languages rather than of migrant languages. Yet, even among the most sturdy migrant languages (Maghrebian Arabic and Kabyle Berber) what *in relative terms* are impressive transmission rates – (70%–80% of Parisian children of two migrant-language-speaking parents say they can speak the language well or very well), as well as the phenomena of migrant-language-speaking parents being replied to in French by their children – ultimately point to ongoing decline which, at best, can be decelerated, but certainly not halted.

In legal terms, the linguistic situation in France is far from straightforward. Because of the fundamental French republican values of indivisibility, oneness, and equality (there is a single French people; demographic minorities defined in terms of distinctions along ethnic, cultural, or linguistic lines are not recognized; one subgroup cannot be treated differently from any other), the situation of languages other than French is in many ways unclear. They do not enjoy official recognition, they are widely stigmatized, and little in the way of reliable statistics is available about the extent of their use. (The figures reported above are perhaps on the conservative side.) Thus, along with no questions about religion and ethnicity, census surveys omit questions of language use, and those studies that have been conducted do not reliably question informants about their level of competence. Similarly, no questions about linguistic background are asked of people seeking to immigrate or be naturalized.

Official intervention in matters of language use has sought to protect French from various perceived threats and goes back to the 1539 edicts of Villers-Cotterêts, which – at a time when barely anyone spoke it – imposed French (instead of Latin) as the language to be used in all administrative and legal contexts, orally and in writing. Political intervention – this time against France's regional heritage languages – continued in revolutionary France with a systematic policy of linguistic unification. With a view to protecting consumers from a potential invasion by English, the 1975 *Loi Bas-Lauriol* imposed the use of French in all public signage and any documentation relating to services or goods, including written and spoken advertising. In 1989, the government created the *Délégation générale à la langue française* (DGLF), tasked with engaging relevant authorities in the promotion of the French language nationally and internationally, while respecting linguistic and cultural diversity and plurilingualism. Its creation was followed by a 1992 amendment to Article 2 of the 1957 constitution, which made French the sole official language – once again a preemptive strike to protect French against progress by English, this time within international bodies – and the 1994 *Loi Toubon*, which updated the *Loi Bas-Lauriol* and extended it to cover official government documents, the media, and education. However, such protectionism toward French in the face of a perceived threat from English has been interpreted as clearly anti-plurilingual. Nevertheless, in 2001 the DGLF was renamed the *Délégation générale à la langue française et aux langues de France*. Now, rather than merely respecting plurilingualism, the organization is to develop it in the name of cultural diversity.

Within the context of the European Union, the European Charter for Regional or Minority Languages was adopted – against the wishes of France – by the Council of Ministers in 1992. It was not until 1999, though, that France signed up to 39 of the Charter's 98 measures, considerably fewer than her neighbors. Specifically, France shied away from recognizing, protecting, or conferring rights on any linguistic minority group. Later, the Constitutional Council prevented the Charter from being ratified by ruling that the Preamble and Article 7 ran counter to the Constitution in that they conferred specific rights to speakers of regional or minority languages. (President Jacques Chirac caused a minor political storm when he rejected a suggestion from Prime Minister Lionel Jospin to amend the Constitution to avoid the problem.) While at least 35 of the Charter's measures were deemed uncontentious, the Council of State further suggested that ratification would have little impact because the measures largely coincided with existing domestic law. Indeed, within the media, legislation passed in 1982 and updated in 2000 obliges public-service broadcasters to promote regional language and culture, and provision by Radio France (radio) and France 3 (television) is

variable in both quantity and quality. Within the independent-radio sector, in contrast, a number of specialized minority-language stations have been set up. The post office even agreed to deliver mail addressed in Breton, Basque, and Occitan, and some road signs are now bilingual!

Much of the battle between monolingualists and plurilingualists has been fought in education. Given that revolutionary France used schools as the tool for imposing French on the entire population, this was understandably the area in which the minority-language campaigners, who began to organize themselves in the 19th century, chose to fight for their cause. Exactly a century after an 1851 circular relating to the *Loi Falloux* ruled that French was the sole language to be used in schools, the first sign of flexibility with respect to the use of heritage languages as a symbol of regionalism came with the rather restrictive 1951 *Loi Deixonne*, which allows primary and secondary schoolteachers to apply for permission to offer optional classes, initially in Breton, Basque, Catalan, and Occitan, later in Corsican, Alsatian, and Gallo. The 1975 *Loi Haby* extends the provision in allowing regional languages to be taught to schoolchildren of all ages, and requires curricula and timetables to be revised as well as teachers to be trained. The 1995 circular 95–086 recommends a wider awareness of regional languages and cultures within schools, and even allows for up to three hours of classes per week through the medium of the regional language, as a way of addressing the need to preserve national cultural heritage. The 2001 decree 2001–733 envisages a consultative regional-language council with the task not only of promoting regional languages and ensuring that their status is not undermined but also of collaborating with regional education authorities in formulating regional-language policy and monitoring how policy is implemented. Things have not always run smoothly: a 2002 order from the department of education establishing bilingual immersion teaching was rescinded by the Council of State on the grounds that because immersion was not *necessary* for teaching regional languages, the general rule that French be used as the *medium* of instruction should be upheld. And, of course, not everyone in regional-language-speaking areas supports the cause, and many doubt the practical value of regional languages. For example, unionists argue that the dialectal variation within Corsican means that the language does not lend itself to use in public examinations. Corsican language teaching regionally has been compulsory at secondary school since 1999: one longitudinal study suggests that support for the initiative actually fell sharply during the first year of implementation!

Estimates of the number of pupils learning regional heritage languages at school range from 110 000 to 335 000. A government report from 2002 suggests that some 225 000 pupils in metropolitan France were taught regional heritage languages in 2001–2002, up 50% from the previous year, but still only about 2% of the total school population. What is clear is that, while the take-up of regional heritage languages (except Gallo) within schools is increasing (especially Basque, Catalan, and Corsican), it is nowhere near as widespread as modern foreign languages such as English and Spanish, or indeed Hebrew and Chinese. In Alsace, rather than promoting Alsatian, the newly enlightened language-teaching policy within primary schools is actually benefiting standard German! It is only in Corsica that regional-language teaching is anything like fully embedded within the curriculum, with 83% of primary schoolchildren exposed to the language and as many as 20% of teenagers including Corsican in their *baccalauréat* diet. Elsewhere, even the rosier pictures are not good for regional language survival: in the Basque country, 80% of schoolchildren are not taught Basque.

The term *franglais* encompasses combinations of French (*français*) and English (*anglais*) of various kinds. First, it refers to any variety that has developed naturally as a mixture of the two languages as a result of long-standing contact. Such varieties are spoken, for example, in New Brunswick (Canada) and northern Maine (United States). Second, the term refers to code switching between the two languages in what in some cases are again long-standing bilingual or diglossic settings. This occurs, for example, in Quebec (Canada), where, especially in Montreal since the 1960s, Anglophones frequently switch to French midsentence, just as Francophones would switch to English. Finally, Franglais refers to the phenomenon whereby native English or French speakers pepper their speech with lexis from the other language for humorous effect, to show off, or because of gaps in their native lexis. The use of French words in English was caricatured by Miles Kington's 'Parlez-vous Franglais?' column in the British satirical periodical *Punch* from the late 1970s and subsequently in a series of books. The reverse phenomenon, which will be our concern here, is taken much more seriously and is most closely associated with Sorbonne philosopher René Étiemble's vitriolic *Parlez-vous franglais?*, first published in 1964.

The term *franglais* encompasses combinations of French (*français*) and English (*anglais*) of various kinds. First, it refers to any variety that has developed naturally as a mixture of the two languages as a result of long-standing contact. Such varieties are spoken, for example, in New Brunswick (Canada) and northern Maine (United States). Second, the term refers to code switching between the two languages in what in some cases are again long-standing bilingual or diglossic settings. This occurs, for example, in Quebec (Canada), where, especially in Montreal since the 1960s, Anglophones frequently switch to French midsentence, just as Francophones would switch to English. Finally, Franglais refers to the phenomenon whereby native English or French speakers pepper their speech with lexis from the other language for humorous effect, to show off, or because of gaps in their native lexis. The use of French words in English was caricatured by Miles Kington's 'Parlez-vous Franglais?' column in the British satirical periodical *Punch* from the late 1970s and subsequently in a series of books. The reverse phenomenon, which will be our concern here, is taken much more seriously and is most closely associated with Sorbonne philosopher René Étiemble's vitriolic *Parlez-vous franglais?*, first published in 1964.

Franglais is primarily a lexical innovation: new lexis has been absorbed and existing lexis is being used differently. Francophones have enriched their lexis by (a) adopting English word forms, especially from commerce (*le shopping*, *le business*, *le discount*, *le leasing*, *le sponsor*); (b) adapting English lexis (*le self* 'self-service cafeteria', *le parking* 'parking lot', *le dressing* 'dressing room', *le loft* 'loft apartment'); and (c) innovating pseudo-English lexis (*le starter* 'choke', *le footing* 'jogging', *le baby-foot* 'table football', *le pressing* 'dry cleaner's' *le lifting* 'face-lift', *le brushing* 'blow-dry', *le planning* 'schedule', *le recordman* 'record holder', *le rugbyman* 'rugby player', *le scratch* 'Velcro').

In addition to embracing English word forms, Francophones have changed the way they use French forms, apparently under the influence of English, either as a faux ami (*un ordre* for *une commande* 'an order', *une opportunité* for *une occasion* 'an opportunity', *du matériel* for *du tissu* 'fabric') or by calquing the syntax of English expressions (*nourrir le chat* 'to feed the cat' for *donner à manger au chat*, *rejoindre l'armée* 'to join the army' for *s'inscrire à l'armée*, *parler sur le téléphone* 'to speak on the telephone' for *parler au téléphone*). According to Duneton (1999: 121), this usage would have shocked just a few decades ago but is now banal.

However, Franglais is alleged to have had influence beyond lexis, too, for example, in the use of unnecessary determiners in appositive contexts (*Berlin, la capitale de l'Allemagne*); prenominal adjectives (*la composition scientifique* > *la scientifique composition*); adjectives as adverbs (*écrire économiquement* > *écrire économique* 'to write economically'). Increased use of passives has also been blamed on English influence. Finally, although Franglais lexis often submits to French stress patterns (breath-group final rather than lexical or foot-based) and orthography (*bouledozère* 'bulldozer', *boum* 'boom', *cédérom* 'CD-ROM'), Franglais has had a minor impact on the phonology and orthography of the language, with increased occurrence of the phones [ʔ] and [ʤ] (otherwise found in borrowings, only) and the graphemes *k*, *y,* and *w.* (Arguably, though, a much more apparent, economy-driven impact on French orthography is being caused by SMS messaging, with unpronounced graphemes dropped (*tabac* > *taba*, *comme* > *kom*), the representation of vowels and consonants simplified (*beau* > *bo*, *qui* > *ki*), and single graphemes used to represent whole words (*c'est/ces/ses* > *c*).

Étiemble's thesis is that, because of its scale, rather than being part of a natural process of dynamic development, the one-way influence of English on French taking place from the mid-20th century onward is, instead, doing unwelcome and irreparable damage to the core of the French language, culturally if not purely linguistically. Duneton (1999) has reached the same conclusion. Whether or not Étiemble is right depends on one's perspective. If one sees language as a mere vehicle for communication, then openness on the part of one linguistic community to the lexical resources of the language of another can only increase expressive power. Contact and mutual influence between Francophones and Anglophones have a history going back a millennium, and the languages are widely believed to be all the richer as a result. More recent longitudinal work by Shana Poplack on the effect of English–French contact on the French language spoken around Ottawa and Hull (Canada) suggests that French has been enriched by the contact, rather than impoverished. If, in contrast, like Étiemble, one sees language as having a role to play in articulating a speech community's social and cultural identity, then excessive influence of English on French arguably undermines French (or at least Francophone) identity. Distinguishing French lexical influence on English from English lexical influence on French, for example, Duneton (1999: 115ff) reported the view that the former reflects middle-class snobbery, the latter, working-class ignorance. The desire to combat this perceived ignorance underlies much of the corpus planning pursued in France in recent decades, with official dictionaries cataloguing approved French alternatives to anglicisms and legislation guaranteeing the use of the French language in a number of contexts.

There are various reasons to believe that the stance adopted by Étiemble is more emotional than rational and similarly Duneton, one of whose grounds for concluding that the heart of the French language is under threat is the observation that Francophones now say *Oops!* – apparently unheard of in 1979 – rather than *Hou là là!* when they drop something! It is likely, for example, that Étiemble overestimated the scale of lexical Franglais. Leeman-Bouix (1994: 29–30) cites a 1965 study that counted 694 English-origin words in the 100 000 lexemes of French (0.7%). Similarly, Étiemble was wrong to claim that Franglais lexis was unwarranted due to the availability of French synonyms. For example, although *faire du shopping* may be as perfect a synonym of *faire des courses* as it is possible to get, Leeman-Bouix (1994: 137–138) justified the use of *challenger* over *adversaire* 'opponent' in TV game shows precisely because it includes the notion of challenge, absent from *adversaire*, and the use of *casting* instead of *distribution* because of the ambiguity of the latter term in the cinema context. Finally, Étiemble was in fact mistaken in some of the claims of English influence he made, for example, *examen-fenêtre* 'the act of examining an

object by the window', blamed by Étiemble (1973: 195) on unwelcome English influence, despite the absence of any evidence to support such an accusation (Goosse, 2000: 131). It is thus difficult to disagree with Hagège (1987: 52) that "English has not impacted upon the hard core of the French language" and Goosse (2000: 141) that the unmarked variety, or varieties, of French is following its course.

A more plausible take on the underlying concerns of Étiemble and other purists hangs on yet another role of language, namely, its at times near-isomorphic relationship with, and reflection of, the status of a nation. There is no need to rehearse here the geopolitics of the 20th century and the way the role of France on the international stage diminished after World War I and particularly World War II. In such a context, Étiemble's talk of an attack by Anglo-American cultural imperialism and Duneton's discourse of an infestation of teeming ants is hardly surprising. Franglais is a rude reminder of the loss of French prestige on the world stage. Thus, the concerns expressed by Étiemble, as well as the status-planning policies embraced by successive French governments since the mid 1960s, not to mention virulent anti-Americanism, can be seen as "a massive overreaction at a time when France's political identity was being redefined" (Battye *et al.*, 2000: 44). Significant in this respect is a contrast between the level of negative reaction to Franglais in France and its broad acceptance in Quebec, for example, where, if anything, the influence of English is even greater.

Frege, Gottlob (1848–1925)

W A de Pater and P Swiggers, Katholieke Universiteit Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Frege was born on November 8, 1848, in Wismar, Germany. He studied mathematics at Jena, then at Göttingen, where he obtained his doctoral degree in 1873. He became Privatdozent at the University of Jena, where he taught mathematics. In 1879 he became extraordinary professor and in 1896 honorary professor. He stayed in Jena until he retired in 1918. He died on July 26, 1925, in Bad Kleinen. Frege's main field of research was mathematics and the philosophy of mathematics, but his lasting contributions are in the field of formal logic and philosophy of language. During his lifetime Frege, who was an introvert and had a very small audience, exerted little influence, but his ideas were diffused by Rudolf Carnap, Bertrand Russell, and Ludwig Wittgenstein. Because of the development of semantic theory and the growing impact of formal logic on linguistic theorizing, his work occupies a central position within contemporary semantic and linguistic theory, epistemology, and philosophical logic.

Frege's work can be seen as the (unfulfilled) realization of his logicist program, which consisted in reducing arithmetic to logic, i.e., in defining arithmetical concepts in terms of logical concepts and in developing a strictly formalist-logical system for arithmetic statements and procedures. His *Begriffsschrift* (1879) was the first important step in the realization of the program. Frege modernized propositional and predicate logic, and provided a notational system for

object by the window', blamed by Étiemble (1973: 195) on unwelcome English influence, despite the absence of any evidence to support such an accusation (Goosse, 2000: 131). It is thus difficult to disagree with Hagège (1987: 52) that "English has not impacted upon the hard core of the French language" and Goosse (2000: 141) that the unmarked variety, or varieties, of French is following its course.

A more plausible take on the underlying concerns of Étiemble and other purists hangs on yet another role of language, namely, its at times near-isomorphic relationship with, and reflection of, the status of a nation. There is no need to rehearse here the geopolitics of the 20th century and the way the role of France on the international stage diminished after World War I and particularly World War II. In such a context, Étiemble's talk of an attack by Anglo-American cultural imperialism and Duneton's discourse of an infestation of teeming ants is hardly surprising. Franglais is a rude reminder of the loss of French prestige on the world stage. Thus, the concerns expressed by Étiemble, as well as the status-planning policies embraced by successive French governments since the mid 1960s, not to mention virulent anti-Americanism, can be seen as "a massive overreaction at a time when France's political identity was being redefined" (Battye *et al.*, 2000: 44). Significant in this respect is a contrast between the level of negative reaction to Franglais in France and its broad acceptance in Quebec, for example, where, if anything, the influence of English is even greater.

Frege, Gottlob (1848–1925)

W A de Pater and P Swiggers, Katholieke Universiteit Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Frege was born on November 8, 1848, in Wismar, Germany. He studied mathematics at Jena, then at Göttingen, where he obtained his doctoral degree in 1873. He became Privatdozent at the University of Jena, where he taught mathematics. In 1879 he became extraordinary professor and in 1896 honorary professor. He stayed in Jena until he retired in 1918. He died on July 26, 1925, in Bad Kleinen. Frege's main field of research was mathematics and the philosophy of mathematics, but his lasting contributions are in the field of formal logic and philosophy of language. During his lifetime Frege, who was an introvert and had a very small audience, exerted little influence, but his ideas were diffused by Rudolf Carnap, Bertrand Russell, and Ludwig Wittgenstein. Because of the development of semantic theory and the growing impact of formal logic on linguistic theorizing, his work occupies a central position within contemporary semantic and linguistic theory, epistemology, and philosophical logic.

Frege's work can be seen as the (unfulfilled) realization of his logicist program, which consisted in reducing arithmetic to logic, i.e., in defining arithmetical concepts in terms of logical concepts and in developing a strictly formalist-logical system for arithmetic statements and procedures. His *Begriffsschrift* (1879) was the first important step in the realization of the program. Frege modernized propositional and predicate logic, and provided a notational system for

expressing all types of relationships between propositions, and offered a formalization of first order predicate calculus. In his following book, *Die Grundlagen der Arithmetik* (1884), Frege provided a not-yet formalized elaboration of logicism. The main idea developed in this work is that numbers can be defined as classes of equivalent classes (hence the *a priori* truth of '$2 + 3 = 5$'). Frege then embarked upon the exhaustive formalization of his program, trying to reduce arithmetic to logic within an axiomatic system. This was the ultimate goal of his *Grundgesetze der Arithmetik*, the first volume of which appeared in 1893 and the second in 1903. But at the time the second volume was published, Frege had already been faced with a paradox in his logical system (the paradox was pointed out to him by Russell), and in spite of his efforts, Frege eventually had to recognize the unrealizability of his reductionist program.

In the process of working out his program, Frege had felt the need to explicate the underlying philosophical views. This required a systematic reflection on notions such as truth, meaning, thought, concept, object, identity, function, and argument. Whereas the 'semantic theory' contained in Frege's *Begriffsschrift* was a poor one, he succeeded in articulating a comprehensive theory of meaning and reference in three articles published in the early 1890s: 'Funktion und Begriff' (1891), 'Über Begriff und Gegenstand' (1892), and 'Über Sinn und Bedeutung' (1892). Although the three articles were, in Frege's view, an informal study (oriented toward aspects of linguistic expression) meant to clarify the aims of logic (the study of laws and properties of thought), they belong to the foundations of modern philosophical logic. Frege himself continued to refer to these articles when, later in his life, he wrote three studies on thought and thought operations ('Der Gedanke,' 'Die Verneinung,' and 'Gedankengefüge,' published between 1918 and 1923). It is important to stress that Frege never referred to his logico-semantic views as constituting a 'philosophy of language' (in fact, as a logician he had a deep mistrust of natural language): whatever he wrote on meaning, reference, assertion, and on linguistic aspects of concepts and judgments was intended to be a less technical exposition of his work in the philosophy of mathematics and in formal logic.

Frege's theory of meaning (and reference) is basically the outgrowth of his reflections on the construction of a notational system for expressing relationships between objects and properties (for Frege's reductionist and very Platonicist ontology only objects and concepts are needed). Objects are expressed by names; as objects, Frege recognizes individuals, classes and truth values. Properties correspond to concepts, expressed by predicative words (*Begriffswörter*, or short: predicates). Predicates are instantiated by individuals (when these are subsumed under a predicate: *Socrates is human*), or are included in a more general predicate (subordination of a predicate under another predicate: *Humans are mortal*). Thoughts (*Gedanken*) are the result of a combination of (object-)names and predicates; they are expressed in sentences, which have a truth value. Predicates are treated as functions to which arguments are linked: a predicative 'function' leaves open one or more places that can be taken in by 'arguments', the variable semantic and syntactic terms filling in the open spots: *speaking* (x), *murdering* (x, y) as semantico-syntactic frames for propositions such as *Brutus is speaking* and *Brutus murdered Caesar*. So Frege treats basic propositional structure in terms of function and argument(s); he was very critical of the traditional analysis into subject and predicate, as it makes no distinction between subsumption and subordination. For the description of the structure of propositions involving operations on the basic function-argument frame, still other expressions are needed, such as 'propositional connectives' and 'quantifiers' (also dealt with by Frege). Frege was aware that apart from assertive propositions or statements there are other types of sentences: commands, wishes, exclamations, etc. He excluded these from his logical investigations, and in fact seems not to have taken much interest in what he called the *Kraft* ('force') of linguistic expressions.

As a logician, Frege stuck to the principle of the part-whole correlation, applying it to the analysis of propositions (in direct relation to their truth value); later, this principle was called the 'compositionality' principle. The principle is used to account for the fact (1) that the truth value of a proposition results from what its component parts stand for; (2) that the (semantic) content of a proposition results from the combined contents of its component parts; (3) that we can construct new propositions out of (significant) parts of formerly uttered propositions.

The crown jewel of Frege's 'philosophy of language' (essentially a logical semantic theory, with a syntactic component later developed by Carnap as 'logical syntax') is his theory of *Sinn* and *Bedeutung*. The terms have been most often translated into English as 'meaning' resp. 'reference' (but also as 'sense' resp. 'meaning'); however, *Sinn* is not strictly (lexical) 'meaning' and *Bedeutung* is not only 'reference' (i.e., a relation) but also 'referent' (i.e., an object: the *Bedeutung* of a proper name is, in Frege's view, the object denotated, and the *Bedeutung* of a proposition

is its truth value) and even 'importance' (Frege's semantic theory has an axiological ring to it, since he also speaks about 'value'). The distinction – which Frege applied to proper names, to (uniquely referring) descriptions, and to (simple/complex) sentences (conditional sentences; indirect speech) – serves to set off (a) the objective idea corresponding to the way an object is presented to us [= *Sinn*] as distinct from all kinds of subjective representations [= *Vorstellungen*] that we can associate with an object; and (b) the object (a referent, class of referents, a truth value) in which the reference achieves its realization [= *Bedeutung*]. Identity statements (such as *The morning star is the evening star*) precisely are cognitively (scientifically) important, because through them we learn that two expressions giving a different presentation of an object refer to the same thing (in this case, the two expressions or names *the morning star* and *the evening star* 'coincide' in the same object, namely, the planet Venus). Of the same object various ways of presentation can be given (like 'Marcus Tullius' and 'Cicero' or of Napoleon: 'the winner of the battle at Austerlitz' and 'the emporer defeated at Waterloo'); the same *Sinn* or way of presentation can, at different moments, correspond to different objects ('the president of the United States'). Although problems remain with the distinction (e.g., what is the *Sinn* of a proper name? How can one make a clear-cut distinction between objective ideas and subjective representations about objects?), Frege's theory of *Sinn* and *Bedeutung* has been of crucial importance for the later study of meaning and reference (specifically for the analysis of proper names and descriptions) and for the logical analysis of sentences. Frege's logic (and reductionist ontology) also inspired later work in logical syntax and semantics as applied to the analysis of truth and to the construction of an ontology.

Freire, Paulo (1921–1997)

A Pérez Pereiro, Arizona State University, Tempe, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

One of the most influential educational thinkers of the 20th century, Paulo Freire became a powerful symbol of the relationship between education and social change, particularly in the Third World. Freire was born on September 19, 1921, in the city of Recife in northeast Brazil, where he grew up in poverty. He succeeded in entering a private high school with a scholarship and became sensitive at an early age of the discrepancies in power and wealth between Brazil's social classes.

Freire entered the University of Recife Law School in 1943 but decided that he should devote himself to education instead. He became the director of education at SESI (Social Service of Industry), a government agency responsible for improving the living standards of workers. He received his Ph.D. in 1959 from the University of Recife with the dissertation 'Present day education in Brazil.' During the 1960s, he became involved in movements for popular education, focusing on adult literacy in rural communities and, in 1963, became the director of the National Literacy Program.

Since at the time literacy was a prerequisite for voter registration, Freire's activities were considered overtly political and, by many in the ruling elite,

is its truth value) and even 'importance' (Frege's semantic theory has an axiological ring to it, since he also speaks about 'value'). The distinction – which Frege applied to proper names, to (uniquely referring) descriptions, and to (simple/complex) sentences (conditional sentences; indirect speech) – serves to set off (a) the objective idea corresponding to the way an object is presented to us [= *Sinn*] as distinct from all kinds of subjective representations [= *Vorstellungen*] that we can associate with an object; and (b) the object (a referent, class of referents, a truth value) in which the reference achieves its realization [= *Bedeutung*]. Identity statements (such as *The morning star is the evening star*) precisely are cognitively (scientifically) important, because through them we learn that two expressions giving a different presentation of an object refer to the same thing (in this case, the two expressions or names *the morning star* and *the evening star* 'coincide' in the same object, namely, the planet Venus). Of the same object various ways of presentation can be given (like 'Marcus Tullius' and 'Cicero' or of Napoleon: 'the winner of the battle at Austerlitz' and 'the emporer defeated at Waterloo'); the same *Sinn* or way of presentation can, at different moments, correspond to different objects ('the president of the United States'). Freire, Paulo (1921–1997)

A Pérez Pereiro, Arizona State University, Tempe, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

One of the most influential educational thinkers of the 20th century, Paulo Freire became a powerful symbol of the relationship between education and social change, particularly in the Third World. Freire was born on September 19, 1921, in the city of Recife in northeast Brazil, where he grew up in poverty. He succeeded in entering a private high school with a scholarship and became sensitive at an early age of the discrepancies in power and wealth between Brazil's social classes.

Freire entered the University of Recife Law School in 1943 but decided that he should devote himself to education instead. He became the director of education at SESI (Social Service of Industry), a government agency responsible for improving the living standards of workers. He received his Ph.D. in 1959 from the University of Recife with the dissertation 'Present day education in Brazil.' During the 1960s, he became involved in movements for popular education, focusing on adult literacy in rural communities and, in 1963, became the director of the National Literacy Program.

Since at the time literacy was a prerequisite for voter registration, Freire's activities were considered overtly political and, by many in the ruling elite,

subversive. In 1964, a military coup ousted President Goulart, and Freire was arrested and held for 70 days on charges of treason. What followed were 16 years of exile. During that time, Freire worked at the Chilean Institute for Agrarian Reform until he took a post at Harvard for a year (1969–1970) and then moved on to Geneva, where he became the educational director of the World Congress of Churches, traveling the world to promote literacy programs and develop further his ideas on education and literacy that he had described in his *Pedagogy of the oppressed* (1972).

A passionate Christian and a Marxist, Freire saw education both as a tool by which ruling classes subdue the masses and as a way of resisting that very oppression. Freire attacked the 'banking' system of education, where the student is viewed as an empty receptacle to be filled with facts, and instead advocated a dialogic or problem-posing approach to teaching, where education is made meaningful because it is related to the real lives and experiences of the learners. The purpose of this style of teaching and learning is to empower learners by making them aware of their own capacity to transform the world. This process, known as conscientization, has been associated with Freire's philosophy of education, although he himself thought the term was often misused.

In 1980, Freire returned to Brazil and began teaching at the Catholic University of São Paulo and the State University of Campinas. He also continued to be involved in adult and mass education programs. In 1986 Freire received the UNESCO Prize for Peace Education, and in 1988 he was appointed minister of education for the city of São Paulo. Paulo Freire died on May 2, 1997, at the age of 75. His work continues to exert a profound influence on educational thought and practice to this day.

French

J C Smith, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

French is a member of the Romance group of Indo-European languages. It forms part of the Gallo-Romance sub-group, along with Occitan and the transitional varieties labeled Franco-Provençal. Modern French can ultimately be traced back to the Latin of northern Gaul, a Latin that was significantly modified by contact with the language of the pre-Roman Celtic inhabitants of the area and the language of the Germanic invaders who occupied the region after the fall of the Roman Empire. Its more immediate ancestor is the medieval dialect of Paris (labeled *francien* by 19th-century scholars), which, as the speech of the major economic and cultural center first of the Île de France and then of a progressively larger administrative unit created by conquest and royal marriages, enjoyed particular prestige; however, in the course of becoming a national standard, this variety was additionally subjected to complex processes of leveling and koineization resulting from large-scale migration to the capital.

Number of Speakers and Geographical Distribution

French is currently spoken (as a first or near-native second language) by approximately 100 000 000 people. In Europe it is the official language of France (population approximately 60 000 000), and is also spoken in the contiguous areas of southern Belgium (roughly 5 000 000 speakers), Luxembourg (500 000), western Switzerland (1 500 000), and the Val d'Aosta region of Italy (35 000). It is one of the two national languages of Canada, where it is the native tongue of almost 7 000 000 people, or between one-fifth and one-quarter of the population – at the provincial level, it is the official language of Québec and has co-official status with English in New Brunswick; smaller numbers of speakers are

subversive. In 1964, a military coup ousted President Goulart, and Freire was arrested and held for 70 days on charges of treason. What followed were 16 years of exile. French is a member of the Romance group of Indo-European languages. It forms part of the Gallo-Romance sub-group, along with Occitan and the transitional varieties labeled Franco-Provençal. Modern French can ultimately be traced back to the Latin of northern Gaul, a Latin that was significantly modified by contact with the language of the pre-Roman Celtic inhabitants of the area and the language of the Germanic invaders who occupied the region after the fall of the Roman Empire. Its more immediate ancestor is the medieval dialect of Paris (labeled *francien* by 19th-century scholars), which, as the speech of the major economic and cultural center first of the Île de France and then of a progressively larger administrative unit created by conquest and royal marriages, enjoyed particular prestige; however, in the course of becoming a national standard, this variety was additionally subjected to complex processes of leveling and koineization resulting from large-scale migration to the capital.

Number of Speakers and Geographical Distribution

French is currently spoken (as a first or near-native second language) by approximately 100 000 000 people. In Europe it is the official language of France (population approximately 60 000 000), and is also spoken in the contiguous areas of southern Belgium (roughly 5 000 000 speakers), Luxembourg (500 000), western Switzerland (1 500 000), and the Val d'Aosta region of Italy (35 000). It is one of the two national languages of Canada, where it is the native tongue of almost 7 000 000 people, or between one-fifth and one-quarter of the population – at the provincial level, it is the official language of Québec and has co-official status with English in New Brunswick; smaller numbers of speakers are

found elsewhere in the maritime provinces, and in Ontario, Manitoba, and Saskatchewan. French is the official language of the French Overseas Territories (most of which are situated in the Caribbean or in the Indian or Pacific Oceans). It is also the official language of several former French colonies, especially in West, North, and Central Africa, although many inhabitants of these countries do not in fact speak French, and, for the majority of those who do, it has the status of a second language. French dialects that differ significantly from the standard language survive in northern France (Picard) and southern Belgium (Walloon), as well as in Normandy. A Norman French dialect is also found in the Channel Islands of Guernsey and Jersey, although the numbers of speakers are fast declining. For two hundred years, from the early 18th century to the early 20th, French was the unrivaled language of international (and especially diplomatic) communication. It also played a crucial role in the establishment and subsequent functioning of the institutions from which the European Union was to emerge. In addition, it has been the vehicle of one of the world's major literatures for over a thousand years. For all of these reasons, French has assumed an importance that transcends the number of its native speakers.

Phonetics and Phonology

A maximal phonemic inventory of contemporary standard European French would include the following: 16 vowels (a front unrounded series /a ɛ e i/; a front rounded series /œ ø y/; a back series consisting of unrounded /ɑ/ and rounded /ɔ o u/; four nasal vowels /ɑ̃ ɔ̃ ɛ̃ œ̃/; and the unspecified vowel schwa /ə/); three glides /j ɥ w/; two liquids /l r/, the former a voiced lateral, the latter usually realized as a voiced uvular fricative [ʁ] or trill [ʀ]; and 16 consonants (bilabial, dental, and velar plosives, voiced and voiceless /p b t d k g/; labio-dental, alveolar, and palatal fricatives, voiced and voiceless /f v s z ʃ ʒ/; and four nasals /m n ɲ ŋ/ – the last found only in some speakers' pronunciation of English loan-words such as *parking*). However, this inventory represents an idealization, and few, if any, speakers exemplify the full system. In particular, a number of vocalic distinctions (especially amongst mid-vowels) have, for many speakers in many contexts, been either obliterated or reduced to phonetically predictable oppositions. While present phonetically, vowel length has ceased to be phonologically significant for virtually all speakers.

The phonetics and phonology of Canadian French differ in significant ways from those of the European language, especially as regards vowels. Vowel length is more salient, and has phonemic value in some contexts (compare *mettre* [mɛtʀ] 'put' vs. *maître* [mɛ:tʀ 'master'); long vowels may become diphthongs. Nasal vowels are less nasal, and have chain-shifted. Short high vowels in closed syllables become lax. Unstressed high vowels in medial syllables may be devoiced or disappear completely.

A strong (although not absolute) phonotactic principle precludes sequences of more than two consecutive consonants (or, utterance-initially, more than a single consonant), excluding syllable-initial [s] and liquids following an obstruent at the end of a cluster. This principle correlates with the presence or absence of schwa in many contexts; in informal speech, schwas will be deleted unless or until such deletion would give rise to an unacceptable sequence of consonants.

The most important and characteristic French sandhi phenomenon is liaison, in which a consonant that is not usually present on the surface in other contexts intervenes between two vowels at a word boundary and blocks hiatus. Historically, liaison arises from the differential disappearance of word-final consonants, which were retained longer before a following vowel than in other contexts. However, a synchronic treatment of the phenomenon must take account of frequent hypercorrections, which suggest that the liaison consonant is no longer underlying, but rather inserted epenthetically. In addition, liaison takes place with only a subset of consonants, and many (though not all) liaisons are highly variable and socially marked. In another sandhi phenomenon, misleadingly termed 'aspirate h' (it does not involve aspiration and may not even involve <h>), expected hiatus-blocking processes, such as elision and liaison, are themselves blocked (compare *l'héritier* [leʁitje] 'the heir' vs. *le hérisson* [ləeʁisɔ̃] 'the hedgehog', but also *le onze* [ləɔ̃z] 'the number eleven').

A strong preference for open syllables means that word boundaries do not always coincide with syllable boundaries. Prosodically, French is characterized by syllable-timing and by an absence of word stress, with tonic stress falling rather on the final syllable of the phonological phrase. Non-final syllables may occasionally bear stress for affective emphasis; otherwise secondary stress is assigned to them according to eurythmic principles. There is a tendency in Canadian French for some phrase-penultimate long syllables to receive stress.

Orthography

The French spelling system is far from phonographic. The 26 letters of the Roman alphabet are insufficient in themselves to represent all the phonemes of the language, and so the inventory of symbols has been augmented by digraphs and diacritics (the acute <´>

and grave <`> accents, which originally distinguished closed and open e, respectively, from schwa, and are occasionally used to distinguish between what would otherwise be homographs, e.g., *la* 'the (fem.)', *là* 'there', *ou* 'or', *où* 'where'; the circumflex <ˆ>, originally placed over a vowel to indicate the omission of a letter that was no longer pronounced, with concomitant lengthening of the vowel; the cedilla <ç>, indicating that <c> is pronounced as [s] before <a>, <o>, or <u>; the tréma <¨>, which, when placed over the second vowel in a sequence, prevents the sequence from being interpreted as a digraph). However, their usage, even in institutionalized normative orthography, is inconsistent. The influence of a late-medieval Latinizing tendency (which, moreover, was often ignorant of the true Latin etyma of French words) is still felt in forms such as *temps* [tɑ̃] (< Latin TEMPVS, compare Old French <tens>) 'time' and *poids* [pwa] (< Late Latin PENSVM, mistakenly traced to Classical Latin PONDVS) 'weight'.

Morphology and Syntax

French is a fusional language. It has three grammatical persons, singular and plural number, and two genders, masculine and feminine. (Nominal case survived into Old French, but was then lost.) The second-person plural forms are also used to encode respect toward a single addressee. Synthetic tenses of the verb (here exemplified by *faire* 'do') are the present (*fais*), future (*ferai*), and past. A morphological distinction of aspect exists only in the past, where a perfective simple past (*fis*) contrasts with an imperfect (*faisais*). The subjunctive, perhaps best described as a 'non-assertive' mood, has a synthetic present (*fasse*) and imperfect (*fisse*). Other indicative tenses, such as the present perfect (*ai fait*), pluperfect (*avais fait*) and future perfect (*aurai fait*), as well as the perfect subjunctive (*aie fait*) and pluperfect subjunctive (*eusse fait*), are realized by combining an auxiliary (usually *avoir* 'have', although *être* 'be' is found with a subset of intransitive verbs) with the past participle. The imperfect and pluperfect subjunctives have disappeared from all but the most formal written registers of the language. A 'future in the past' (*ferais*, *aurais fait*), used in reported speech, doubles as a conditional mood, found in the apodosis of irrealis conditional sentences. This form also conveys attenuative values, such as politeness and evidentiality, and is coming to rival the subjunctive as an exponent of non-assertive modality.

French generally exhibits more analytic exponence than other Romance languages. Unlike Italian, Spanish, and Portuguese, it has lost productive diminutive, augmentative, and superlative morphology. In everyday spoken language, the simple past tense (*fis*) has been ousted by the present perfect (*ai fait*), and there is evidence that a similar process is affecting the future, with the synthetic form (*ferai*) yielding to an analytic 'go to do' construction (*vais faire*). Save in exceptional cases, the singular/plural distinction in nouns and adjectives has become inaudible, with the loss of final [s], (although it continues to appear in writing) and the number of a noun is effectively indicated by some other item, usually a determiner.

Both determiners and adjectives agree with the noun. Determiners precede the noun, and attributive adjectives usually follow it, although they may also precede, especially when they have an affective nuance or a metaphorical interpretation. At sentence level, the basic word order of formal written French is SVO, but the frequent dislocations and topicalizations found in speech and in the informal written language suggest that French may be moving away from a word-order determined by grammatical functions, such as subject and object, toward one that reflects discourse-prominence.

Unlike most Romance varieties, French is not a pro-drop language, and an explicit subject is required in almost all non-imperative sentences. Subject-marking often involves a pre-verbal clitic pronoun; other clitics may mark the direct object, the indirect object, and some types of adjunct. The exact status of these clitics is the topic of much debate, with some scholars seeing them as developing into verbal affixes.

In more formal styles, interrogation is conveyed by inversion of the verb with a subject-clitic. Everyday language uses the interrogative particle *est-ce que* or declarative word-order with rising intonation. Very colloquial varieties, especially in Canada, may use a postverbal interrogative particle *-ti* or *-tu*.

In earlier stages of the language, negation was indicated by the preverbal negative marker *ne*. This marker could be reinforced by a positive-polarity item (thus *personne* 'person' > 'no one', *rien* 'thing' > 'nothing'), including *pas* 'step', which came to be a default filler of this slot and was semantically bleached. Nowadays, *ne* is generally absent from everyday spoken language, leaving the original reinforcing element as the sole marker of negation.

Vocabulary

Significant external influences on the vocabulary of French have included Frankish (during the early Middle Ages), medieval Latin, Italian (especially during the 16th century), and, latterly, English (giving rise to the hotly debated phenomenon of *franglais*). Colonial contact led to the absorption of several words from North African Arabic. Internal

derivational processes include affixation, conversion, and back-formation. Two phonological processes that have proved lexically significant are clipping (e.g., *prof* < *professeur* 'teacher') and *verlan* (inversion of the order of syllables – the name, from *l'envers* 'the reverse', exemplifies the process). The latter phenomenon, which originated in low-socioeconomic-status immigrant areas in the northern suburbs of Paris, but which spread beyond these confines to become widespread in the speech of young people, and which has even penetrated the standard language, is a significant sociolinguistic development, while the outcome of some inversions has contributed to our understanding of French syllable structure.

French Guiana: Language Situation

E Camargo, Centre for Research on Indigenous Languages of America, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Characterized by a situation of plurilingualism with over 20 languages in use, French Guiana includes, among its population, Amerindians, Antilleans, Asians, Creoles, Bushinengues, French, and Hmong, as well as more recent immigrants, all of whom contribute to this overseas department of France's linguistic and cultural diversity. Several of these languages have only recently been introduced, such as Hmong (Yao-Miao family), established in the 1970s.

French, the official language, is used mainly in the government and the schools; however, knowledge of French is not necessary for everyday communication. Although most of the members of the younger generation of all minority groups speak French today, the great majority of children do not have French as their first language, which creates learning difficulties. As a result, the Council of National Education, in partnership with the French Centre of Research in Indigenous Languages of America (CELIA-CNRS/IRD), has implemented a training program with 'bilingual mediators' from six regional languages, aiming to help children learn the official teaching language.

In the media broadcasts, the only regional language which is used is Guianese Creole, although a year ago there were still broadcasts in Kali'na (Carib), Palikur and Ndyuka.

Regional Languages

According to the European Charter for Regional or Minority Languages, the French State lists ten regional languages for French Guiana: three Creole languages, six Amerindian languages, and Hmong (see Figure 1). Work on descriptive linguistics is in progress on most Amerindian and Bushinengue languages. The sociolinguistic situation and the future of these languages are critical, because several are endangered: The number of speakers is low, and there are no policies to increase their status as part of French Guiana's linguistic and cultural heritage.

Creole Languages

Three of the Creole languages spoken in French Guiana are considered regional languages: Guianese Creole, Saramaccan, and Aluku-Ndyuka-Paramaccan. The three languages that make up Aluku-Ndyuka-Paramaccan are very similar to each other and so must be regarded as varieties of only one language.

Guianese Creole Guianese Creole (or Kreol Gwiyanè) is spoken by about 50 000 speakers in French Guiana and another 3000 speakers in Brazil, where it is also referred to as Patwua, Crioulo, or Caripuna. It is spoken in the coastal area and in the area of Lower Oyapock, as well as in Brazil's Uaça area. There are slight dialectal distinctions between Western (surrounding Saint-Laurent) and Eastern French Creole. It has an important tradition and literature.

Guianese Creole is a French-based creole, relatively close to Antillean Creole, and is widely spoken by Amerindians, Bushinengues, Chinese, Brazilians, and Haitian Creoles as a lingua franca. However, in the western area of French Guiana, Guianese Creole can no longer be considered the most widespread language of communication; Bushinengue languages, especially Sranan tongo, are now used most widely there. Recently, a strong revitalization movement in the schools with 'mediators' trained in regional languages and cultures has been supporting the use of Guianese Creole, but its sociolinguistic situation has not been well studied yet. The first study on Guianese Creole linguistics dates to 1872.

In the Brazilian area of Uaça, Guianese Creole is the Caripuna group's mother tongue and is also used by other Amerindians living in this area.

Saramaccan and Aluku-Ndyuka-Paramaccan Originating in Suriname, Black Maroons or Bushinengue languages spoken in French Guiana – Aluku-Ndyuka-Paramaccan and Saramaccan – are called *nenge(e) tongo*. They are characterized by two subgroups of creole: one English-based and the other English relexified toward Portuguese. The Maroon communities remain mainly on the French Guiana and Suriname border. On the coast live 29 800 speakers, with an additional 7400 speakers in the interior. At least 8% of Maroons live in the Netherlands: 100 Aluku, 400 Paramaka, 4500 Ndyuka, and 4000 Saramaka. The term 'taki-taki,' used for all these languages, has a degrading meaning.

Aluku (or Boni) is spoken by 5900 speakers in French Guiana. It is a communication language on the Middle Maroni River area (Maripasoula, Apatou, Papaïchton). Some Aluku live in Cayenne and Kourou. Paramaccan is spoken by 2800 Pamaka speakers in French Guiana and by 2800 in Suriname. They live on the Middle and Lower Maroni River bank. Ndyuka (or Aukan, Okanisi) is spoken by 14 000 speakers in French Guiana and 32 000 in Suriname, who live among the Paramaka. Ndyuka is also spoken by the Aluku and Pamaka people.

Saramaccan (or Samaka) is the most distinct of the Bushinengue languages; 37% of its lexicon is relexified toward Portuguese. It is spoken by 14 500 speakers in French Guiana and 32 000 speakers in Suriname who live in the coastal area and also in the interior.

Amerindian Languages

Amerindian languages are part of three linguistic families in French Guiana (Table 1). All Amerindian groups can communicate in the official language of the country where they live, as well as in the Amerindian and Creole languages with which they are in contact. In French Guiana, descriptive linguistics studies of most of these languages are in progress.

Arawak Family Only 10% of the Arawakan population speaks this language. It is spoken mainly by old people and by very rare young over 35 years old. In French Guiana, less than 20 people still speak it, although some degree of revitalization has been observed. There is great need for a Linguistic survey (descriptive and documentation) of this language. The Arawak language spoken in French Guiana and the Guajiro and the Paraujano languages spoken on

Figure 1 Regional languages in French Guiana. From Goury (2001).

Table 1 Linguistic families in the Amerindian languages

Linguistic family	*Language name*	*Other names*	*Location and population*
Arawak	Arawak	Lokono	600 people in French Guiana, 700 in Suriname, 5000 in Guyana (the most outnumbered group), and a few persons in Venezuela
	Palikur	Parikwaki, Ulukwa	1100 people in French Guiana and 1200 in Brazil
Cariban	Apalai	—	Less than 30 speakers in French Guiana and less than 200 in Brazil
	Kali'na	Caribe, Galibi, Karib	2700 speakers in French Guiana, 3000 in Suriname, 480 or more in Guyana, 12 000 in Venezuela, and 30 in Brazil
	Wayana	Formerly Roucouyen, Urukuyana	800 speakers in French Guiana, 200 in Brazil, and 500 in Suriname
Tupi-guarani	Emerillon	Teko	400 speakers in French Guiana
	Wayampi	—	1270 speakers in French Guiana (510 at Trois Saut and 770 at Camopi) and 686 scattered in 40 villages in Brazil

the Caribbean West Coast present many affinities and can be considered to be a homogeneous dialectal unity.

Palikur speakers refer to this language as Aukwayene, Pa'ikwene, or Parikwene. It originated from the Uaça area in Brazil and differs by only 100 words from kiaptunka, an extinct ceremonial language.

Cariban Family A few Apalaí families moved from Brazil to French Guiana in the late 1960s and again in the early 1990s and intermarried with the Wayana and Trió. The Apalaí language (Apalai: French/English writing, Aparai: Brazilian writing) contains important loanwords from Tupi-Guarani languages. It is not included in the official inventory of regional languages and is considered an endangered language. A Linguistic survey (descriptive and documentation) is needed.

The Kali'na group's name has been at the origin of the name of its linguistic family, Cariban. There is a dialect spoken on the Lower Maroni called Tilewuyu. There are several works on Kali'na sociolinguistics, and there is a Kali'na oral literature as well.

Wayana originated from Brazil. Its speakers have intermarried with other Cariban groups (Apalaí, Trió), as well as Tupi-Guarani ones (Emerillon, Wayampi). On the Brazilian side, a significant number of loanwords are taken from the Apalaí language.

Tupi-Guarani Family Emerillon is the only Amerindian language spoken exclusively in French territory and among the Wayampi (on the Camopi area) and Wayana (on the Maroni and Tampoc rivers). There are quite a few bilingual speakers of Wayana-Emerillon. Wayampi, Aluku, and French are also spoken in this area. Emerillon is an endangered language, and a survey of it is in progress.

Wayampi originated from the Xingu river (Amazon right bank) and was established on the Amapari, Araguari (Upper Ipitinga), and Upper Jari/Cuc rivers in the 18th century. Between 1967 and 1981, the speakers living near the Upper Jari/Cuc rivers scattered among other Wayampi and Wayana villages in Brazil, and in Oyapock in French Guiana. Intermariage occurred with speakers of Wayana and Emerillon. There are dialectal variants and various loanwords from Wayana, French (Creole), and Brazilian Portuguese.

The Hmong

The Hmong, living in French Guiana, established communities mainly in Cacao (1975) and in Javouhey (1977), where there are literacy classes in Hmong. White Hmong is the dominant dialect spoken in French Guiana. Originally from Laos, Hmong speakers lack a knowledge of French, which holds back their progress in school. A strong Laotian cultural heritage remains among the old people. Some Hmong speak Vietnamese.

Other Languages

Other Creole, Indo-European, and Sino-Tibetan languages are spoken in French Guiana, although the vehicular language of these communities remains Guianese Creole. Brazilian, Portuguese, and Haitian Creole are the immigrant languages most spoken. Most people living in French Guiana are bilingual.

Sranan Tongo language is a koïne language of Surinam spoken mainly as a lingua franca by the population on the French Guiana and Suriname border made up of Bushinengue, Indian, Creole, Javanese, and Chinese people. This English-based Creole has a significant Dutch lexicon, which had

been partially relexified toward Portuguese. Sranan is mutually intelligible with Ndyuka, but mutually unintelligible with Saramaccan.

There are a large number of speakers of French-based Creole in French Guiana. Antillean Creole is spoken by 7000 speakers from Antilles (Guadeloupe, Martinica) who live on the coastal areas around the main cities. It has an important literary tradition, and there are literature and linguistics written in Guadeloupean and Martiniccan. Haitian Creole is spoken by 30 000 Haitian emigrants who now live mainly in Cayenne neighborhoods. This French-based Creole is characterized by a merger of French structural and West African languages features. English Creole from Guyana and Creole from the island of St Lucia and from Reunion are also spoken.

Among Indo-European languages, Portuguese and Spanish are the most widely spoken in French Guiana. Officially, Portuguese is spoken by 15 000 Brazilians, but there may be as many as 30 000 speakers. Since 2002, Spanish has been spoken by the increasing number of South American immigrants, mainly Peruvians and Dominicans.

Asian languages are represented by Chinese, which is spoken by 3000 speakers in French Guiana and 6000 in Suriname. The community arrived at the end of the 19th century and beginning of the 20th century from southeastern and eastern China and was established in the main cities (coastal and countryside areas). Lao is spoken by 150 to 200 people living at Roura commune and in Kourou. Hmongs, emigrants from Laos, also speak Lao. Javanese and Vietnamese are also spoken.

Hindustani, Lebanese, and Dutch English are also spoken in French Guiana.

French Polynesia: Language Situation

D T Tryon

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 3, p. 1305, © 1994, Elsevier Ltd.

French Polynesia lies between 7° and 28° S latitude and 131° and 156° W. longitude. Its constituent parts are five archipelagos, namely, the Society Islands, the Tuamotus, the Marquesas, the Gambiers, and the Australs. It has a total population of 188 814 according to the 1988 census, the most recent (1992) complete census available for the archipelago. Within French Polynesia there are five indigenous Polynesia languages spoken, in addition to French, several Chinese dialects, predominantly Hakka, and to a lesser extent English.

The Polynesian languages spoken are Tahitian, Tuamotuan, Marquesan, Mangarevan (Mangareva), and Rapan (Rapa). Tahitian is the principal language of the region. It is spoken by 115 000 speakers, or almost 70% of the population, and is widely used and understood throughout French Polynesia. Tahitian is spoken principally in the Society Islands, with only minor dialect differences between the Windward and Leeward Islands. It is also spoken in the Austral Islands. Tuamotuan is spoken in most of the islands of the Tuamotu archipelago, a series of coral atolls to the northeast of the Society Islands. There are eight dialects of Tuamotuan, with some notable differences in vocabulary between distant atolls, for example, Napuka and Anaa. Tuamotuan has approximately 10 000 speakers. Marquesan is spoken in the Marquesas Islands, situated about 1200 km northeast of Tahiti, by some 7500 resident speakers in two rather marked dialects, one centered around Nuku Hiva in the northwest and the other around Hiva'Oa in the southeast. Mangarevan is spoken by no more than 620 Polynesians in the Gambier group of islands far to the southeast. Rapan is spoken on Rapa (pop. 480), some 1500 km south of Tahiti. There Tahitian has made considerable inroads, with few Rapan speakers remaining in the 1990s whose language is not heavily Tahitianized.

The official languages are French and Tahitian. Literacy is estimated at 95%. The languages of government/administration are French and Tahitian, as they are for broadcasting and television. The medium of education is mainly French, although Tahitian is also used in some schools at primary level. Marquesan is also taught in the Marquesas group. The main foreign language, apart from French, is English.

French Southern Antarctic Lands: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Situated in the southern sector of the Indian Ocean, the Southern Lands comprise two archipelagos, Iles Crozet and Iles Kerguelen, as well as two volcanic islands, Ile Amsterdam and Ile Saint-Paul. There is no indigenous population nor are there permanent settlements in the Southern Lands, which are used only for research concerned principally with meteorology and the local fauna. The Antarctic lands correspond to the Adelie Land, a thin strip of about 500 000 sq km in the Antarctic continent discovered and claimed

by the French in 1840. This last claim is, however, neither recognized nor denied by the Antarctic Treaty, which governs the whole of Antarctica. The French Southern and Antarctic Lands are an overseas territory of France and are administered from Paris. The approximately 150–200 researchers – the numbers vary between summer and winter – present in the Lands are mainly French speakers from France and Reunion Island. Vacant positions are advertised in French and research papers are also primarily published in French.

French Lexicography

P Bogaards, Leiden University, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The Beginnings

As in other European countries, French lexicography was at first bilingual. The first publication that can be considered a dictionary appeared in 1531 under the title *Dictionarium seu Latinae linguae Thesaurus . . . cum Gallica fere interpretatione* (i.e., an inventory of the Latin language with translations into French). Its author, the humanist Robert Estienne (otherwise known as Robertus Stephanus) (*see* **Stephanus, Robertus (ca. 1503–1559)**), was to reedit and expand his dictionary several times. In 1539 Estienne published an inversion of his dictionary under the title *Dictionaire françois-latin contenant les motz et les manieres de parler françois tournez en latin*. This French–Latin dictionary went through several editions, which, with the help of collaborators and later successors, were enlarged with more and more technical terms, regional vocabulary, and words used by great contemporary writers such as Du Bellay and Ronsard. Other items, such as definitions and etymologies, were added over the years. Whereas the fourth edition (1573) was still called *Dictionaire françois-latin*, the fifth edition (1606), compiled by Jean Nicot, was presented under the title *Thresor de la langue françoyse* and included some 18 000 entries. This dictionary constitutes the first description of the French lexicon. It was not a monolingual dictionary, however, as all comments were given in Latin. This type of dictionary is sometimes called 'faux bilingue.'

In the meantime other bilingual, and often multilingual, dictionaries had appeared. A. Calepino or Calepinus had published a dictionary with five languages in 1545 and one with ten languages (Latin, Greek, Hebrew, Italian, French, Spanish, German, English, Polish, and Hungarian) in 1585. The first bilingual dictionary with a 'modern' vernacular as target language was the *Dictionaire françois-flamand*, published in 1562 by G. Meurier. There were other bilingual dictionaries to follow for English (1567) by L. Harryson and Spanish (1575) by C. Oudin. A more complete French–English dictionary was compiled by R. Cotgrave on the basis of a recent edition of Nicot's *Thresor*. It appeared in 1611 under the title *A dictionarie of the French and English tongues* and covered about 40 000 items.

In 1635 Richelieu, cardinal and statesman under Louis XIII, founded the Académie Française, which had as its primary remit to work out 'des règles certaines à notre langue' (sure rules for our language). The list of works to be undertaken included, after a grammar, a rhetorics, and a poetics, a dictionary of the French language. This dictionary was to be published at the end of the century (1694). As the need for a good monolingual dictionary was felt by many, P. Richelet published his *Dictionnaire français* in 1680, while A. Furetière, member of the Académie but not satisfied with the work of his fellow Academicians, published his *Dictionnaire universel* in 1690. As the Académie Française had the monopoly of the first monolingual dictionary of French, both Richelet's and Furetière's dictionaries had to appear outside the country (in Switzerland and Holland, respectively).

Richelet's dictionary contained most of the characteristics of a modern monolingual dictionary: definitions, usage labels, examples, and quotations, and it described several registers, such as colloquial and vulgar, technical and regional terms, archaisms and neologisms. Like Furetière's dictionary, which was more extensive and contained encyclopedic elements, Richelet's dictionary was organized as an alphabetical list. The *Dictionnaire de l'Académie Françoise*, on the other hand, continued the older tradition of the Latin glossaries, which had an organization that was

essentially based on roots and necessitated many cross-references. This arrangement, which was much criticized, did not reappear in later editions. The lack of technical terms in the dictionary of the Academy was compensated for by the *Dictionnaire des arts et des sciences* published by another Academician, Th. Corneille, in 1694.

During the 18th century, the dictionary by Furetière, along with the *Dictionnaire de Trévoux* (1704), a new version of Furetière's dictionary compiled by the Jesuits of that town, was reedited several times, as was the case with a number of other dictionaries that had been compiled during the preceding century. The main new event of the 18th century was the publication, from 1751 to 1780, of the *Encyclopédie ou dictionnaire raisonné des sciences, des arts et des métiers* (35 vols) (*see* **Encyclopédie**). This major work by D. Diderot and J. Le Rond d'Alembert included almost 72 000 entries and comprised eleven volumes with thousands of illustrations. It firmly established one of the characteristics of French lexicography: the encyclopedic dictionary. One other dictionary should be mentioned, the *Dictionnaire critique de la langue française* (1787) of J.-F. Féraud, which constitutes one of the best and most systematic inventories of the language of the 18th century.

Maturity: Littré, Larousse, Robert

In the first half of the 19th century there was a tendency toward collection of the maximum number of entries, for example in the dictionary by P.-C. Boiste (first edition 1800, 14th edition 1857) or the *Dictionnaire national* by L.-N. Bescherelle (1843). Dictionaries of this type tend to include ever more words, including neologisms and archaisms (and even nonexistent words), as well as many appendices with lists of synonyms, homonyms, rhymes, and essays on versification or pronunciation. On the other hand there are abridged editions of existing dictionaries in which one finds large word lists with little information on the words presented. Both types of dictionaries can be seen as affected by the growing numbers of children attending school. Besides, there were dictionaries that foreshadowed the innovations that were to take place later in the history of French lexicography: Laveaux (1820) and Poitevin (1856) were firmly based on literary examples, Dochez (1859) presented etymologies and usage in a systematic way, and Lafaye (1858) and Boissière (1862) were the first dictionaries that enabled users not only to find the meaning of words but also to search for words for objects or concepts.

Real innovations were introduced by the three lexicographers mentioned in the heading of this section. Emile Littré and Pierre Larousse were contemporaries, but their dictionaries illustrate two fundamentally different directions in French lexicography.

Littré, who published his *Dictionnaire de la langue française* from 1863 to 1873 (4 vols), presented his description of the French language with some 250 000 quotations, mainly taken from the classical writers of the 17th century and with a marked neglect of more contemporary sources. He also took into account the growing body of knowledge about etymology and the history of the French language. Littré's dictionary is an excellent example of philological and historical lexicography. Because of the importance given to the use of the words, it is essentially a 'dictionnaire de langue'. As to the philological tradition, one should mention also the dictionary of Darmesteter and Hatzfeld (1890–1900), which goes systematically from the 'etymological or primitive sense' to the present-day meaning.

Pierre Larousse, who began his career as a schoolteacher, was much more interested in the modern use of the language. In his *Grand dictionnaire universel du XIXe siècle*, published from 1865 to 1890 (15 vols plus two supplements), he took advantage of the language of contemporary writers such as Victor Hugo or Emile Zola. But there is also a wealth of encyclopedic information: every entry has two sections, one devoted to the language and the other, which is often very long, to descriptions of the outside world. Larousse's dictionary exemplifies the other type of French lexical reference work called a 'dictionnaire de choses,' or encyclopedic dictionary.

About a century later, Paul Robert managed to create a new blend of a number of these characteristics. His *Dictionnaire alphabétique et analogique de la langue française* (1953–1964, 6 vols) is a 'dictionnaire de langue,' based as it is on an enormous collection of quotations, taken this time from a variety of contemporary sources, journalistic as well as literary, and from modern writers as well as classics. At the same time, as is announced in its title, it is an onomasiological dictionary that leads the user from known to unknown elements, thanks to a system of analogical cross-references. It was the first general dictionary to introduce such a system.

After the publication of the Robert, the focus on the language itself, which had been somewhat neglected since Littré (finished in 1873 and never updated), was taken up by others. The *Grand Larousse de la langue française* (1971–1978, 7 vols) should be mentioned in this context, as well as two dictionaries by the linguist Jean Dubois: the *Dictionnaire du français contemporain* (1966) and the *Lexis* (1975), which presented different uses of the same

form as homonyms and grouped derivatives under a single base form. A project that was financed by the French government and managed by Paul Imbs and Bernard Quemada was the *Trésor de la langue française* or TLF (1971–1994, 16 vols). For this project, which was the first to use new technologies on a large scale, extensive literary sources, from the Revolution until about 1960, as well as a minority of technical and scientific texts, were perused.

This survey would not be complete without mentioning the *Dictionnaire explicatif et combinatoire* or DEC (1984–2000) by I. Mel'čuk and his collaborators in Montréal, Canada. Up to now four volumes with several hundred lexical items have been published. This project introduced a system of explicit definitions, exhaustive syntactic descriptions of every individual 'lexème', and a limited list of 'lexical functions', such as *Magn* for the class of intensifiers or *Incep* for expressions that indicate the beginning of a process.

The State of the Art

At the beginning of the 21st century, the lexicographic landscape for French is rich and varied, although there are also gaps and deficiencies. For instance, there is no dictionary describing the collocations of French, and for synonyms there are only dictionaries presenting lists of forms, no commented inventories of words having similar meanings, with the recent exception of the *Dictionnaire des synonymes* of Larousse (1992, 2003).

The market for general one-volume dictionaries is dominated by the *Petit Larousse* (first edition, 2005), a 'dictionnaire de choses', and the *Petit Robert* (first edition, 1967), a 'dictionnaire de langue.' Both are issued annually in an updated version, the *Petit Larousse* for more than a century now. Next to the *Petit Robert*, there is the *Petit Robert des noms propres* or PR2 (first edition, 1974), which treats one type of encyclopedic information. The *Dictionnaire Hachette* contains every year a list of neologisms awaiting definitive integration in the dictionary.

Although most dictionaries belong to the didactic type of texts, some are explicitly meant for special groups of speakers. Features such as defining style, the use of illustrations, and the choice of words to be treated bring the *Robert junior* (1993), the *Dictionnaire Hachette Benjamin* (1996), the *Larousse du collège* (1995) and other dictionaries published by Nathan more into the reach of young speakers of French.

In the field of dictionaries for native speakers of other languages, the *Dictionnaire du français. Référence. Apprentissage* (1999), for a number of reasons, does not meet the needs of potential users nor the standards set by the learners' dictionaries for English. The same goes for the *Dictionnaire du français usuel* (2002), which was compiled for use by native speakers of French as well as for nonnative speakers. On the other hand, the *Robert & Collins junior bilingue* (2002) by M. Back is an excellent though limited dictionary for young French learners of English at the elementary stage. The *Dictionnaire d'apprentissage du français des affaires* (2000), by a group of Belgian teachers, is very interesting and innovative in the use of a sound corpus, the introduction of an explicit defining style inspired by the Dictionnaire explicatif et combinatoire, and the systematic treatment of collocations.

As for French outside France, it has been studied in recent decades and turns up more and more frequently in general dictionaries, especially in the *Robert*. But dictionaries devoted to these varieties have been published also: French in North America (among others Bergeron, 1980; Auger *et al.,* 1988; Boulanger, 1992; Meney, 1999), in Africa (AUPELF, 1981, 1995, 1998), or in Europe (Knecht, 1997, 2000 for Switzerland), as well as a dictionary of regionalisms (Rézeau, 2001).

For the history of the French lexicon there is always the monumental *Französisch etymologisches Wörterbuch* (1921, 25 vols) by W. von Wartburg. As a complement to this exhaustive dictionary, one can find a lively description of the evolution of French words in A. Rey's *Dictionnaire historique de la langue française* (1992, 2 vols).

Popular varieties of French are described in the *Dictionnaire du français non conventionnel* by J. Cellard and A. Rey, and an inventory of recent words can be found in the *Dictionnaire des mots contemporains* by P. Gilbert. Both date from 1980 and have not had any successors since then, although *Le dico du sport* and *Le dico de la violence* by A. Doillon (2002) partially fill this gap.

Bilingual dictionaries with French as one of the languages exist for all more important languages as well as for many lesser-known languages. The best ones seem to be those that are compiled in collaboration with publishing houses in other countries, such as the *Robert & Collins* and the *Oxford Hachette* series of English–French French–English dictionaries. Unfortunately, the vast majority of these dictionaries, even those for the biggest market (English and French) are bidirectional, trying to serve in a single volume native speakers of both languages. There exist some specialized bilingual dictionaries such as the *Robert & Collins du management* (1992).

Most general monolingual and bilingual dictionaries are now available in electronic form, in most cases as CD-ROMs or DVD-ROMs. These are all conversions of existing paper dictionaries. A growing

number of important dictionaries are available online. This is, for instance, the case for the TLF and the *Dictionnaire de Trévoux*. Other historical dictionaries, such as Nicot's *Thresor*, the 18th-century *Encyclopédie*, the *Dictionnaire de l'Académie*, or the *Grand dictionnaire universel* of Pierre Larousse, are published as CD-ROMs by the publishers Redon and H. Champion. The only corpus of texts that is available for research or for other purposes is Frantext, the somewhat outdated and mainly literary corpus that has been compiled in the context of the TLF.

Freud, Sigmund (1856–1939)

R Pozzo, University of Verona, Verona, Italy

© 2006 Elsevier Ltd. All rights reserved.

A physician and the founder of psychoanalysis, Freud claimed from the beginning that the newly founded discipline was to take over the role of philosophy and to transform metaphysics into metapsychology. The science of unconscious mental processes and a particular method of treating nervous disorders, psychoanalysis is no special sector of medicine; it is psychology, more precisely 'depth psychology,' inasmuch as it reaches beyond consciousness toward the unconscious. Freud considered psychoanalysis the link between psychiatry and several of the arts and the sciences, including biology, anthropology, the study of religion, education, literary history, and linguistics.

Freud was born on May 6, 1856, at Freiberg in the Republic of Tchechien, which was then part of the Austro-Hungarian Empire. His family moved to Vienna in 1860, where Freud spent almost all his life. In 1938 he was forced to move to London after the annexation of Austria to Germany; he died there on September 23, 1939, a few weeks after the beginning of World War II. In 1873 he entered the University of Vienna, where he studied medicine while also sitting in Franz Brentano's philosophical courses. After receiving his *Habilitation* in 1885, he went to Paris to study hysteria and the use of hypnosis with Jean-Martin Charcot at the Salpêtrière hospital. In 1886 he resolved to give up his academic career; he married and opened a private practice with a specialty in neurology. In 1887 he started exchanging letters with Wilhelm Fliess (Freud, 1985), setting up the frame of his own autoanalysis. Literary success came with the publication of *The interpretation of dreams* (Freud, 1953–1974, vols 4–5) in 1900. In 1902 he was appointed extraordinary professor at the University of Vienna (he was to rise to the rank of ordinary professor only in 1920, and not without great resistance) and began to gather a devoted following; in 1908 the first psychoanalytical congress took place; in 1909 Freud made, together with Carl Gustav Jung, the first international presentation of his theories, at Clark University in Massachusetts; and in 1910, during the second psychoanalytical congress, the International Psychoanalytical Association was founded. In 1923 Freud was diagnosed with cancer of the jaw, a result of years of cigar smoking; he would have 30 operations over the next 16 years to treat the progressive disease. He received the Goethe Prize in 1930 for his cultural studies.

The fundamental thesis of psychoanalysis is that the mind works by affectively charged complexes of ideas. Psychoanalysis makes possible the understanding not only of pathological phenomena but also of social institutions, artistic reactions, moral systems, religion. *The psychopathology of everyday life*, written in 1901 (Freud, 1953–1974, vol. 6) explained a number of linguistic phenomena by means of the subconscious, which is the part of the mind that witnesses

French Polynesia: Language Situation

D T Tryon

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 3, p. 1305, © 1994, Elsevier Ltd.

French Polynesia lies between 7° and 28° S latitude and 131° and 156° W. longitude. Its constituent parts are five archipelagos, namely, the Society Islands, the Tuamotus, the Marquesas, the Gambiers, and the Australs. It has a total population of 188 814 according to the 1988 census, the most recent (1992) complete census available for the archipelago. Within French Polynesia there are five indigenous Polynesia languages spoken, in addition to French, several Chinese dialects, predominantly Hakka, and to a lesser extent English.

The Polynesian languages spoken are Tahitian, Tuamotuan, Marquesan, Mangarevan (Mangareva), and Rapan (Rapa). Tahitian is the principal language of the region. It is spoken by 115 000 speakers, or almost 70% of the population, and is widely used and understood throughout French Polynesia. Tahitian is spoken principally in the Society Islands, with only minor dialect differences between the Windward and Leeward Islands. It is also spoken in the Austral Islands. Tuamotuan is spoken in most of the islands of the Tuamotu archipelago, a series of coral atolls to the northeast of the Society Islands. There are eight dialects of Tuamotuan, with some notable differences in vocabulary between distant atolls, for example, Napuka and Anaa. Tuamotuan has approximately 10 000 speakers. Marquesan is spoken in the Marquesas Islands, situated about 1200 km northeast of Tahiti, by some 7500 resident speakers in two rather marked dialects, one centered around Nuku Hiva in the northwest and the other around Hiva'Oa in the southeast. Mangarevan is spoken by no more than 620 Polynesians in the Gambier group of islands far to the southeast. Rapan is spoken on Rapa (pop. 480), some 1500 km south of Tahiti. There Tahitian has made considerable inroads, with few Rapan speakers remaining in the 1990s whose language is not heavily Tahitianized.

The official languages are French and Tahitian. Literacy is estimated at 95%. The languages of government/administration are French and Tahitian, as they are for broadcasting and television. The medium of education is mainly French, although Tahitian is also used in some schools at primary level. Marquesan is also taught in the Marquesas group. The main foreign language, apart from French, is English.

French Lexicography

P Bogaards, Leiden University, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The Beginnings

As in other European countries, French lexicography was at first bilingual. The first publication that can be considered a dictionary appeared in 1531 under the title *Dictionarium seu Latinae linguae Thesaurus . . . cum Gallica fere interpretatione* (i.e., an inventory of the Latin language with translations into French). Its author, the humanist Robert Estienne (otherwise known as Robertus Stephanus) (*see* **Stephanus, Robertus (ca. 1503–1559)**), was to reedit and expand his dictionary several times. In 1539 Estienne published an inversion of his dictionary under the title *Dictionaire françois-latin contenant les motz et les manieres de parler françois tournez en latin*. This French–Latin dictionary went through several editions, which, with the help of collaborators and later successors, were enlarged with more and more technical terms, regional vocabulary, and words used by great contemporary writers such as Du Bellay and Ronsard. Other items, such as definitions and etymologies, were added over the years. Whereas the fourth edition (1573) was still called *Dictionaire françois-latin*, the fifth edition (1606), compiled by Jean Nicot, was presented under the title *Thresor de la langue françoyse* and included some 18 000 entries. This dictionary constitutes the first description of the French lexicon. It was not a monolingual dictionary, however, as all comments were given in Latin. This type of dictionary is sometimes called 'faux bilingue.'

In the meantime other bilingual, and often multilingual, dictionaries had appeared. A. Calepino or Calepinus had published a dictionary with five languages in 1545 and one with ten languages (Latin, Greek, Hebrew, Italian, French, Spanish, German, English, Polish, and Hungarian) in 1585. The first bilingual dictionary with a 'modern' vernacular as target language was the *Dictionaire françois-flamand*, published in 1562 by G. Meurier. There were other bilingual dictionaries to follow for English (1567) by L. Harryson and Spanish (1575) by C. Oudin. A more complete French–English dictionary was compiled by R. Cotgrave on the basis of a recent edition of Nicot's *Thresor*. It appeared in 1611 under the title *A dictionarie of the French and English tongues* and covered about 40 000 items.

In 1635 Richelieu, cardinal and statesman under Louis XIII, founded the Académie Française, which had as its primary remit to work out 'des règles certaines à notre langue' (sure rules for our language). The list of works to be undertaken included, after a grammar, a rhetorics, and a poetics, a dictionary of the French language. This dictionary was to be published at the end of the century (1694). As the need for a good monolingual dictionary was felt by many, P. Richelet published his *Dictionnaire français* in 1680, while A. Furetière, member of the Académie but not satisfied with the work of his fellow Academicians, published his *Dictionnaire universel* in 1690. As the Académie Française had the monopoly of the first monolingual dictionary of French, both Richelet's and Furetière's dictionaries had to appear outside the country (in Switzerland and Holland, respectively).

Richelet's dictionary contained most of the characteristics of a modern monolingual dictionary: definitions, usage labels, examples, and quotations, and it described several registers, such as colloquial and vulgar, technical and regional terms, archaisms and neologisms. Like Furetière's dictionary, which was more extensive and contained encyclopedic elements, Richelet's dictionary was organized as an alphabetical list. The *Dictionnaire de l'Académie Françoise*, on the other hand, continued the older tradition of the Latin glossaries, which had an organization that was

number of important dictionaries are available online. This is, for instance, the case for the TLF and the *Dictionnaire de Trévoux*. Other historical dictionaries, such as Nicot's *Thresor*, the 18th-century *Encyclopédie*, the *Dictionnaire de l'Académie,* or the *Grand dictionnaire universel* of Pierre Larousse, are published as CD-ROMs by the publishers Redon and H. Champion. The only corpus of texts that is available for research or for other purposes is Frantext, the somewhat outdated and mainly literary corpus that has been compiled in the context of the TLF.

A physician and the founder of psychoanalysis, Freud claimed from the beginning that the newly founded discipline was to take over the role of philosophy and to transform metaphysics into metapsychology. The science of unconscious mental processes and a particular method of treating nervous disorders, psychoanalysis is no special sector of medicine; it is psychology, more precisely 'depth psychology,' inasmuch as it reaches beyond consciousness toward the unconscious. Freud considered psychoanalysis the link between psychiatry and several of the arts and the sciences, including biology, anthropology, the study of religion, education, literary history, and linguistics.

Freud was born on May 6, 1856, at Freiberg in the Republic of Tchechien, which was then part of the Austro-Hungarian Empire. His family moved to Vienna in 1860, where Freud spent almost all his life. In 1938 he was forced to move to London after the annexation of Austria to Germany; he died there on September 23, 1939, a few weeks after the beginning of World War II. In 1873 he entered the University of Vienna, where he studied medicine while also sitting in Franz Brentano's philosophical courses. After receiving his *Habilitation* in 1885, he went to Paris to study hysteria and the use of hypnosis with Jean-Martin Charcot at the Salpêtrière hospital. In 1886 he resolved to give up his academic career; he married and opened a private practice with a specialty in neurology. In 1887 he started exchanging letters with Wilhelm Fliess (Freud, 1985), setting up the frame of his own autoanalysis. Literary success came with the publication of *The interpretation of dreams* (Freud, 1953–1974, vols 4–5) in 1900. In 1902 he was appointed extraordinary professor at the University of Vienna (he was to rise to the rank of ordinary professor only in 1920, and not without great resistance) and began to gather a devoted following; in 1908 the first psychoanalytical congress took place; in 1909 Freud made, together with Carl Gustav Jung, the first international presentation of his theories, at Clark University in Massachusetts; and in 1910, during the second psychoanalytical congress, the International Psychoanalytical Association was founded. In 1923 Freud was diagnosed with cancer of the jaw, a result of years of cigar smoking; he would have 30 operations over the next 16 years to treat the progressive disease. He received the Goethe Prize in 1930 for his cultural studies.

The fundamental thesis of psychoanalysis is that the mind works by affectively charged complexes of ideas. Psychoanalysis makes possible the understanding not only of pathological phenomena but also of social institutions, artistic reactions, moral systems, religion. *The psychopathology of everyday life*, written in 1901 (Freud, 1953–1974, vol. 6) explained a number of linguistic phenomena by means of the subconscious, which is the part of the mind that witnesses

the emergence of the unconscious in conscious life. The forgetting of names, *parapraxias* such as slips of the tongue, mistakes in reading and writing, omitted acts, and other forms of resurgence into social reality of what has been suppressed do not happen by chance; they are strictly determined by psychical forces (Timpanaro, 1976). *Jokes and their relation to the unconscious*, written in 1905 (Freud, 1953–1974, vol. 8) made it clear that most creations of our mind are nothing but psychology that is projected outside, and it is the task of psychoanalysis to retranslate imaginary constructs into metapsychology.

Freud's discoveries not only provided an extension of the uses to which the various languages might be put; they also suggested a range and a new reordering of symbolism that could be applied in various ways to literature. *The relation of the poet to day-dreaming*, written in 1908 (Freud, 1953–1974, vol. 4) made the point that the unconscious, which is the underworld into which rejected wishes and thoughts are cast, surrounds the conscious life of man and apparently influences and colors it at every point. The artist's creations, works of art, were the imaginary gratifications of unconscious wishes, just as dreams are, and like them they were in the nature of compromises, since they too were forced to avoid any open conflict with the forces of repression.

The question of the logical status of psychoanalytic theories has dominated philosophical debates about Freud (Levy, 1996). Freud recognized the distinction between the verbal claim that the terms 'mental' and 'conscious' are interchangeable and the factual claim that mental phenomena are in every instance conscious. However, his denial that there are mental occurrences from which the unconscious is absent seems indeed to cut off any theoretical falsification. Wittgenstein made the point that psychoanalysis imposes interpretations, rather than unfolding them as it claims. For him, psychoanalytic interpretation involves a predetermined explanation imposed on a mental state that reduces it to something familiar and common where, nevertheless, the assent or non-assent of the patient is supposed to be normative. Psychoanalysis becomes then a kind of religion, one that does not even realize that that is what it is (Wittgenstein, 1966). On Freud's behalf, one can note, however, that not even an empty wrangle over words is empty of unconscious motivation that needs to be brought to life. To agree with the stipulation that 'mental life' must not be stretched beyond the range of application of the word 'conscious' means to silence psychoanalysis (Lazerowitz, 1977).

Fries, Charles Carpenter (1887–1967)

J G Fought, Diamond Bar, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Fries was born in Reading, Pennsylvania. He received an A.B. from Bucknell University in 1909, briefly attended the Divinity School at the University of Chicago, and then returned to Bucknell, where he received an M.A in Classics. He taught there until 1920. He then obtained a Ph.D. from the University of Michigan in 1922, and taught there until his retirement in 1958.

Teaching English, both to native and to non-native speakers, was central to his life's work. In addition to addressing English teaching directly (1927, 1945) and attempting to interpret linguistics for English teachers (1955, 1961), he produced not one but two descriptive treatments of informal American usage, each based on a large corpus of data. The first (1940) used letters sent to a U.S. government agency; the second (1952) used a large number of recorded telephone calls. In the best tradition of American descriptive linguistics, he chose to gather data from popular rather than elite usage. In his analysis, he

the emergence of the unconscious in conscious life. Fries was born in Reading, Pennsylvania. He received an A.B. from Bucknell University in 1909, briefly attended the Divinity School at the University of Chicago, and then returned to Bucknell, where he received an M.A in Classics. He taught there until 1920. He then obtained a Ph.D. from the University of Michigan in 1922, and taught there until his retirement in 1958.

Teaching English, both to native and to non-native speakers, was central to his life's work. In addition to addressing English teaching directly (1927, 1945) and attempting to interpret linguistics for English teachers (1955, 1961), he produced not one but two descriptive treatments of informal American usage, each based on a large corpus of data. The first (1940) used letters sent to a U.S. government agency; the second (1952) used a large number of recorded telephone calls. In the best tradition of American descriptive linguistics, he chose to gather data from popular rather than elite usage. In his analysis, he

used substitution in frames and other standard techniques for mapping out the differences that produced different reactions. These led him, for example, to a system of four principal form classes or parts of speech in English.

To some linguists, his theoretical position and linguistic target seemed loosely defined. He was primarily interested not in formal analysis aimed at other linguists, but rather in speakers' reactions to what they heard, in each hearer's understanding of the verbal signal – results that would be helpful in teaching English. His research showed that indeterminacy and imperfect communication were normal phenomena; however, academic linguistics was not ready to digest the implications of such findings. Similarly, to many in the literary arm of the English professoriat, such a theory and such data must have seemed wrongly conceived: vernacular English presented in nontraditional terms and categories was of no interest in literary studies. Consequently, Fries was inaccurately branded. Some theory-oriented linguists saw him as too involved in applied work; the literary English faculty viewed him, as they did many other linguists, as a 'behaviorist,' a tag that was even less appropriate for him than for many others. However, ESL teachers all over the world have appreciated and honored him for decades.

Frings, Theodor (1886–1968)

W H Veith, Universität Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Theodor Frings was born in Dülken, a small town of the lower Rhine area near Mönchen-Gladbach, as the son of a bookbinder. He studied 'Germanistics' and 'Romanistics' in Marburg, a combination decisive for his further fundamental research. He received his doctor's degree from the University of Marburg in 1911; his thesis dealt with the lower Rhine dialects. In Bonn, he qualified as a university lecturer ('Habilitation') with a book on the Rhenish accent, in 1915. First, he was associate professor of Dutch and Low German language and literature at the University of Bonn, then, at the same university, full professor of German philology with respect to the Dutch, Low German, and Rhenish languages. In the years 1927–1957, he was full professor of German language and literature at the University of Leipzig.

The dynamics of language in history was the major field of interest to Theodor Frings. In teaching and studying, this was his practice. German as a language had to be contrasted with neighboring languages, in the West with Dutch (e.g., Frings, 1944, 1948, 1956) and French (e.g., Frings, 1932, 1939, 1956), and in the East with Slavic languages (e.g., Frings, 1936 and many doctoral theses initiated by Frings, among them those on East German onomastics). The idea to have all East German dialect areas described led to a great number of monographs coming from his students.

In the Rhineland, the territories of the late Middle Ages were responsible for dialect boundaries. This was 'history' as a factor. That the state frontiers were barriers of communication was not further discussed. Frings accumulated examples of a transfer of the vocabulary from Romance languages into German; he even managed to show the 'streets' that the loanwords took to intrude into German, e.g., of *Presse* 'winepress'. But to characterize these events, a precise terminology was lacking if compared with Hugo Schuchardt or, later on, Uriel Weinreich.

To Frings, the explanation of language change was the 'external' history. Sound changes (e.g., Frings, 1939) and loan words (e.g., Frings, 1932, 1956) were explained this way. The basis of the (later on) standard German language as described by Frings was scientifically well accepted: the regional basis is east Germany (Thuringia, Saxony, Silesia). Also, the external history there was the reason for the linguistic results: settlers from three German dialect areas came to the east; by dialect mixture, they ended up

used substitution in frames and other standard techniques for mapping out the differences that produced different reactions. These led him, for example, to a system of four principal form classes or parts of speech in English.

To some linguists, his theoretical position and linguistic target seemed loosely defined. That the state frontiers were barriers of communication was not further discussed. Frings accumulated examples of a transfer of the vocabulary from Romance languages into German; he even managed to show the 'streets' that the loanwords took to intrude into German, e.g., of *Presse* 'winepress'. But to characterize these events, a precise terminology was lacking if compared with Hugo Schuchardt or, later on, Uriel Weinreich.

To Frings, the explanation of language change was the 'external' history. Sound changes (e.g., Frings, 1939) and loan words (e.g., Frings, 1932, 1956) were explained this way. The basis of the (later on) standard German language as described by Frings was scientifically well accepted: the regional basis is east Germany (Thuringia, Saxony, Silesia). Also, the external history there was the reason for the linguistic results: settlers from three German dialect areas came to the east; by dialect mixture, they ended up

with a compromise system of language that later on reached the level of a national language. Their oral compromise language corresponded with the written language of that area so that both variations could found the standard German language. This result is one of the outstanding achievements of Theodor Frings.

Frisian: Etymology

R H Bremmer, University of Leiden, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The etymology of Frisian has not been as much studied as Dutch and German, even though Western Frisian is recognized as an official language beside Dutch in the Netherlands. Even less attention has been given to Eastern Frisian and Northern Frisian, both spoken in Germany, but with only limited official status there.

The etymological study of Frisian has mainly been ancillary. The data helped to serve the interests of etymologists of Dutch and English especially. As early as the beginning of the 17th century, the philologist Johannes de Laet (1581–1649) studied Old Frisian to gain a better understanding of the roots of Dutch (Bremmer, 1998: 155). Likewise, Franciscus Junius (*see* **Junius (Francisci Filius), Franciscus (1591–1677)**) mastered Frisian for similar reasons (Breuker, 1998). Like Kiliaan (*see* **Kiel/Kiliaan, Cornelis van (1530–1607)**), Junius used Frisian for comparison with mainly Dutch and English.

New philological interest in Frisian came with the Romantic movement. Rasmus Rask (*see* **Rask, Rasmus Kristian (1787–1832)**) and Jacob Grimm (*see* **Grimm, Jacob Ludwig Carl (1785–1863)**) gave full recognition to Frisian in their explorations of Germanic. Joseph Bosworth, author of the *Dictionary of the Anglo-Saxon language* (1838) exerted himself to get as much Frisian in it as possible (Stanley, 1990). Karl von Richthofen's dictionary of 1840, through its inclusion of Germanic cognates, was a major step toward the etymology of the earliest phases of Frisian. Ferdinand Holthausen's *Altfriesisches Wörterbuch* (1925) consistently provided etymological information by including cognates for each entry, occasionally adding bibliographical information. Unfortunately, Hofmann's revision of this dictionary did not extend to updating the etymological component. Exceptional are the concordantial glossaries compiled by Buma (1949) for his editions in the series *Oudfries(ch)e taal- en rechtsbronnen*, notably *Die brokmer rechtshandschriften*, which he provided with extensive etymologies. Ahlsson (1960) presented a full survey of the abstract nouns with their derivations. Lendinara (1999) did much to make good the neglect of Old Frisian in 20th-century lexicographic works, such as J. Pokorny's *Indogermanisches etymologisches Wörterbuch* (1959) and W. Lehmann's *Gothic etymological dictionary* (1986). Faltings (1996) compensated somewhat for the relative neglect of Frisian in Heidermann's etymological dictionary of Germanic primary adjectives. For his Old Frisian data, Orel (2003) relied on the Holthausen dictionary, thus partly recycling wrong or outdated information (see Bremmer, 2005). A recent online etymological dictionary, based on the First Riustring Manuscript only, is Boutkan (2004–).

Akademy, founded in 1938, set as its main goal the compilation of a large-scale dictionary after the model of the *Woordenboek der Nederlandsche Taal* (*WNT*). The first volume of the *Wurdboek fan de Fryske Taal* (*WFT*) appeared in 1984. 19 out of 26 planned volumes have followed, and completion is scheduled for 2008. Its scope is more modest than the *WNT*. The *WFT* describes the vocabulary between 1800 and 1975, definitions are in Dutch, pronunciation is given in a slightly adapted IPA, important dialect variants are signaled, and ample citations with sources are provided for each entry. However, the *WFT* gives little etymological information. Other Akademy products are two good concise dictionaries: Frisian–Dutch (Zantema, 1984) and Dutch–Frisian (Visser, 1985). All lexicographical work at the Fryske Akademy has been computerized. A spin-off of Zantema (1984) is a word index in reverse order by Dykstra *et al*. (1992). Jørgensen and Hoekema (1968) is a West Frisian–Danish / Danish–West Frisian pocket dictionary. Dykstra (2000) is a fairly comprehensive West Frisian–English dictionary, also providing a concise English–Frisian word list and grammar of Frisian in English. Fort (1980) is a dictionary with grammar of Saterlandic in German (without pronunciation). Kramer (1992–) is compiling a large-scale trilingual East Frisian dictionary (definitions in West Frisian, English, and German) with pictures (and pronunciation in IPA). The center for the lexicography of North Frisian is the Nordfriesische Wörterbuchstelle at the University of Kiel. The great diversity of the North Frisian dialects together with the relatively few speakers of each dialect has seriously impeded lexicographical work. Yet most dialects have received dictionaries since the late 19th century. Some recent dictionaries include Sjölin (1994), for the Wiedingeharde dialect, and Sjölin *et al*. (2002), for the Mooring dialect, both Mainland); *Fering-Öömrang Wurdenbuk/ Wörterbuch der friesischen Mundart von Föhr und Amrum* (Anon. 2002) is a good concise tool for the insular dialects of Föhr and Amrum. Although for many years a comprehensive dictionary for all the North Frisian dialects has been in preparation, it seems unlikely that such a work will be completed in the foreseeable future.

Despite the advances in the various branches of Frisian studies, the situation is still far from ideal, which also unfortunately mars our understanding of, for instance, the word geography and etymology of (West) Germanic, to which Frisian has much to contribute because of its relatively isolated position and linguistic conservatism.

with a compromise system of language that later on reached the level of a national language. Their oral compromise language corresponded with the written language of that area so that both variations could found the standard German language. This result is one of the outstanding achievements of Theodor Frings.

Frisian: Etymology

R H Bremmer, University of Leiden, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The etymology of Frisian has not been as much studied as Dutch and German, even though Western Frisian is recognized as an official language beside Dutch in the Netherlands. Even less attention has been given to Eastern Frisian and Northern Frisian, both spoken in Germany, but with only limited official status there.

The etymological study of Frisian has mainly been ancillary. The data helped to serve the interests of etymologists of Dutch and English especially. As early as the beginning of the 17th century, the philologist Johannes de Laet (1581–1649) studied Old Frisian to gain a better understanding of the roots of Dutch (Bremmer, 1998: 155). Likewise, Franciscus Junius (*see* **Junius (Francisci Filius), Franciscus (1591–1677)**) mastered Frisian for similar reasons (Breuker, 1998). Like Kiliaan (*see* **Kiel/Kiliaan, Cornelis van (1530–1607)**), Junius used Frisian for comparison with mainly Dutch and English.

New philological interest in Frisian came with the Romantic movement. Rasmus Rask (*see* **Rask, Rasmus Kristian (1787–1832)**) and Jacob Grimm (*see* **Grimm, Jacob Ludwig Carl (1785–1863)**) gave full recognition to Frisian in their explorations of Germanic. Joseph Bosworth, author of the *Dictionary of the Anglo-Saxon language* (1838) exerted himself to get as much Frisian in it as possible (Stanley, 1990). Karl von Richthofen's dictionary of 1840, through its inclusion of Germanic cognates, was a major step toward the etymology of the earliest phases of Frisian. Ferdinand Holthausen's *Altfriesisches Wörterbuch* (1925) consistently provided etymological information by including cognates for each entry, occasionally adding bibliographical information. Unfortunately, Hofmann's revision of this dictionary did not extend to updating the etymological component. Exceptional are the concordantial glossaries compiled by Buma (1949) for his editions in the series *Oudfries(ch)e taal- en rechtsbronnen*, notably *Die brokmer rechtshandschriften*, which he provided with extensive etymologies. Ahlsson (1960) presented a full survey of the abstract nouns with their derivations. Lendinara (1999) did much to make good the neglect of Old Frisian in 20th-century lexicographic works, such as J. Pokorny's *Indogermanisches etymologisches Wörterbuch* (1959) and W. Lehmann's *Gothic etymological dictionary* (1986). Faltings (1996) compensated somewhat for the relative neglect of Frisian in Heidermann's etymological dictionary of Germanic primary adjectives. For his Old Frisian data, Orel (2003) relied on the Holthausen dictionary, thus partly recycling wrong or outdated information (see Bremmer, 2005). A recent online etymological dictionary, based on the First Riustring Manuscript only, is Boutkan (2004–).

The etymology of Middle Frisian (1550–1800) fares even worse, mainly because it has not yet been described lexicographically. Good explorations are Brandsma (1936), an exhaustive study of the verbs in the works of the Renaissance poet Gysbert Japix (1603–1666), providing etymologies for each verb, and Van der Kuip (2003), for a study of the lexicon of the *Burmania proverbs* (ca. 1610). Many obscure words from this period have been etymologized by Buma in a series of word studies called 'Wurdsneuperijen,' most of them published in *Us Wurk*.

For Modern Frisian the situation is far from ideal. Buma (1969) announced an etymological dictionary, and included as a sample the entries for 'A'. The *Wurdboek fan de Fryske Taal* (Van der Veen, 1984–), whenever possible, refers to the Dutch cognate, enabling the reader to find the etymology in Dutch dictionaries. For words lacking such cognates, reference is given to relevant studies, if any. The only fully etymologized dialect of Western Frisian is that of the island of Schiermonnikoog (Frisian Skiermûntseach) (Spenter, 1968). Hoekema (1979) is a Frisian word index on Spenter's work, thus supplying a key to the etymology of numerous Standard Frisian words. Van der Veen (1993) surveyed the many steps to be taken before an adequate etymological dictionary of Western Frisian can be written.

For Eastern Frisian and Northern Frisian there are no etymological dictionaries. Useful information can be found in the studies of Löfstedt (e.g., 1963–1969), Faltings (1993), and Århammar (e.g., 1988).

The relative importance of Frisian in a wider Indo-European context was pointed out by Århammar (1972–1973). Bremmer (1988, 1992) showed the significance of Frisian for the etymology of English and Dutch, respectively. Wollmann (1990) and Dekker (2000) demonstrated the relevance of Frisian for the recovery of the early Latin loans into Germanic and rebuked the arbitrariness with which etymologists of the major Germanic languages have hitherto treated Frisian.

Frisian Lexicography

R H Bremmer Jr, Universiteit Leiden, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

In modern times Frisian never attained the status of a national language. On the contrary, for centuries it has been a minority language in the Netherlands, Germany, and, until the 1860s, Denmark. The social status of Frisian is reflected in the still inadequate state of its lexicography.

Frisian is divided into West Frisian, spoken in the Dutch province of Fryslân (ca. 470 000 speakers), East Frisian, spoken only in Saterland, Niedersachsen (*ca.* 1500 speakers), and North Frisian – both Insular and mainland – spoken in Schleswig-Holstein (*ca.* 10 000 speakers). West Frisian is the most fully developed branch, while the other two are restricted to mainly agrarian communities. The traditional periodization, especially for West Frisian, is Old (1200–1550), Middle (1550–1800), and Modern (1800–).

Old Frisian

The lexicography of Frisian began with its historical stages. In 1786, Tileman Wiarda (1746–1826), a lawyer, published a dictionary of Old Frisian, based on a limited number of texts. Far more exhaustive, and still useful today, was Karl von Richthofen's *Altfriesisches Wörterbuch* (1840), based on his *Friesische Rechtsquellen* (1840), an edition of practically all then known Old Frisian texts. Von Richthofen (1811–1888), a legal historian and pupil of Jacob Grimm (see Grimm, Jacob Ludwig Carl (1785–1863)), arranged his dictionary alphabetically, entering compounds under the simple form. Through the contextual illustration of words, dictionaries of comparable languages such as J. Bosworth's *Dictionary of the Anglo-Saxon Language* (1838) and E. G. Graff's *Althochdeutscher Sprachschatz* (1834–1846) excelled in clarity of presentation. Willem L. van Helten (1907) supplied important corrections and additions to von Richthofen's work. These were incorporated in the work of Ferdinand Holthausen (1925), a glossary rather than a dictionary, and corrected and improved by Dietrich Hofmann (1985). At his death (1998), Hofmann left behind an almost complete new concise dictionary of Old Frisian, which is now being prepared for publication at the University of Kiel. The Fryske Akademy, in cooperation with the Frisian Institute (University of Groningen), is working on a large-scale comprehensive Old Frisian dictionary, completion of which is scheduled for ca. 2015. An important tool for Old West Frisian is Buma's (1996) concordance-based dictionary.

Middle Frisian

Middle West Frisian, above all influenced by the Renaissance poet Gysbert Japix (1603–1666), was first surveyed (in Dutch) by Ecco Epkema (1754–1832), a classical philologist, in 1824. Although individual glossaries have appeared since then, most recently Van der Kuip (2003), a comprehensive dictionary is still wanting. However, all known texts have been stored in a database and lemmatized. This material is accessible at the Fryske Akademy and is being used for a hardcopy dictionary, to appear ca. 2008. The scanty remains of Middle East Frisian have not been assembled yet, but can be found for the greater part in König (1911), Möllencamp (1968), and Remmers (1993). Written tradition started only in the 19th century for the North Frisian dialects, with a few exceptions. Holthausen (1921) edited one of the extant 18th-century handwritten glossaries.

Modern Frisian

A milestone in the emancipation and standardization of Modern West Frisian was reached with Waling Dijkstra, whose dictionary (1896–1914) gave an adequate inventory of the Frisian vocabulary, with definitions in Dutch and frequent illustrations and citations. Dijkstra (1821–1914), a bookseller and prolific popular writer, was able to incorporate into his dictionary both the published and unpublished lexicographical work of the great philologist Joost Hiddes Halbertsma (1789–1869). The Fryske

species, the male first changes some characteristics of its advertisement call before switching to a second kind of vocalization, the aggressive call or encounter call (Wells, 1977). In comparison to advertisement calls, aggressive calls are much less stereotyped, and variation in such properties as call duration and rate of calling may even be correlated with the probability that the encounter will escalate to a physical fight (Figure 2; Grafe, 1995). Males of some species produce complex calls that have two or more distinct elements. Experiments show that one part is directed toward females and the other toward potential rivals. Because females of most species that have been tested strongly prefer advertisement calls to aggressive calls (see the review in Gerhardt and Huber, 2002), these compound calls have the advantage of retaining their attractiveness to females while providing what is perhaps a stronger warning to rivals than the advertisement call alone.

After physical contact, the identification of gender and sexual receptivity is mediated by release calls. Males are notoriously indiscriminate in trying to clasp and mate with other frogs of comparable size that move near them in a breeding aggregation. Males that are clasped produce release calls, which often have an acoustic structure similar to that of aggressive calls. Unreceptive females – those that are not yet ready to lay eggs or that have already mated – also give release calls, which have a structure similar to that of male release calls. Distress calls may also be produced by individuals of both genders when they are captured by a predator. Unlike all other signals in the repertoire, these calls are made with the mouth open. Distress calls may startle the predator and allow the frog to escape.

Figure 2 Oscillograms of a graded series of calls produced by an African tree frog (*Hyperolius marmoratus*). The first call in the series (left, A) is produced when males are calling in relative isolation and would be considered the advertisement call. In vocal interactions, males add increasing numbers of cycles of modulation (pulsing) and increase call duration as the level of aggression escalates. The last two or three calls could be considered aggressive calls (B), which might be produced as an immediate response to a strong threat. Reproduced with permission from Gerhardt and Huber (their Figure 9.3A), originally adapted from Grafe (1995, Figure 4).

Mechanisms of Call Production

Most species of frogs and toads use pressurized air from the lungs to excite vibration of the vocal cords, which are situated in the larynx. These vibrations are then radiated from specialized vocal sacs, which inflate during each call and which in a few species may serve as secondary visual cues. The vocal sac does not add energy to the sound but acts as an impedance-matching device that increases the efficiency of radiation. That is, sound – and especially low frequencies with long wavelengths – radiates more effectively from the large surface of the vocal sac than from the relatively tiny membranes that constitute the vocal cords. Species without vocal sacs can nevertheless produce reasonably loud calls. Species with long-duration calls can shuttle air back and forth from the lungs to the vocal sac without having to inhale again. In a few species, sound is produced during inspiration, and there is strong evidence that in the bullfrog (*Rana catesbeiana*), sound is efficiently radiated by the large external eardrums of the male (Purge, 1997). Specialized mechanisms of calling have also been described in highly aquatic species such as pipids and South African clawed frogs, which call while submerged.

The frequency content of the call is determined mainly by the physical properties (size, stiffness, tension, mode of vibration) of the vocal cords. In signals with a broadband spectrum (e.g., Figure 1B, 1D) the vocal cords can selectively resonate and hence 'color' the frequency content of the final output. The temporal properties of the call are shaped by active or passive modulation. In active modulation, one sound is produced for each contraction of the body wall musculature that forces air from the lungs. In passive modulation, the airflow from the lungs is continuous, but the airstream is pulsed, because the larynx acts as a pressure-sensitive relaxation oscillator. That is, the larynx is held closed by muscle tension, but air forces it open periodically, at which time the vocal cords are excited in vibration. In some species, calls are produced by both active and passive modulation. The temporal properties of the calls of these heterothermic animals are almost always temperature dependent, and female preferences are affected by temperature in a parallel fashion – a phenomenon termed *temperature coupling* (Gerhardt, 1978b).

Vocal Development and Learning

In most frogs and toads, there is no parental care. Moreover, young frogs typically metamorphose from tadpoles after males of their own species are no longer present or calling. Thus, a juvenile frog is more likely to hear the calls of other species than calls of its own

species. For this reason, the current dogma is that the vocalizations of frogs and toads are unlearned, as are the selective responses of females to these signals. A few experiments in which frogs were raised from tadpoles in acoustic isolation and even in environments where they were exposed to the calls of other species have supported this hypothesis. The calls produced by these experimental subjects were typical of conspecific males that are recorded in nature (e.g., Doherty and Gerhardt, 1984). However, such experiments have not been conducted with species with very long breeding seasons or in which tadpoles overwinter. Here young frogs would have ample opportunities to associate with and hear the calls of conspecific adults. There is also no evidence that young anurans learn to respond or discriminate among different sound patterns during development to sexual maturity. However, adult male bullfrogs habituate (a form of learning) to the calls of their territorial neighbors, so frogs at least have the ability to learn to recognize sounds that differ in relatively subtle ways.

Recognition of Advertisement Calls: Behavior and Function

Advertisement calls potentially convey information about the caller to receivers of the same and the opposite gender. Although a few studies have been concerned with distinguishing these kinds of calls from others in the repertoire, such as aggressive calls (Gerhardt, 1978a), most work has focused on the acoustic properties that allow females to recognize conspecific calls and perhaps to choose a particular male from among nearby callers. More recently, studies of male bullfrogs have identified properties of advertisement calls that underlie the discrimination of the calls of familiar neighbors and strange males (Bee and Gerhardt, 2001a, 2001b). The functional aspects of these behavioral studies have been complemented by statistical analyses that (1) quantified the pattern of variation in acoustic properties within and between biological classes of concern (species, populations, individuals, types of signals), and (2) correlated variation in acoustic properties with attributes of the caller that might constitute biologically important information for decision making by the receiver (Gerhardt, 1991). For example, if the mostly strongly emphasized (dominant) frequencies of the calls of one species broadly overlap those of the calls of another species in the same environment, then this property is unlikely to be useful for females of either species to distinguish between conspecific and heterospecific calls. If variation in dominant frequency is correlated with body size, then this property could be reliable for discriminating among individuals in the context of mate choice or territorial defense – a form of honest advertisement.

Relevant and Irrelevant Properties

Frogs and toads are superb subjects for testing ideas about the function and discriminability of the signal properties that might convey biologically important information. Gravid females reliably show positive phonotaxis (movement toward a sound source) to speakers playing back attractive sounds and indicate their preferences among two or more different sounds emitted by separate speakers by hopping on or near one speaker. Male frogs respond to playbacks by altering the timing and rate of calling or by switching to another type of call. Whereas most preference tests on females are conducted in arenas, in which gravid females are placed after capture, most playbacks to males take place in a field, where a speaker can be placed close to a calling male without disturbing it.

As in the earliest experiments by ethologists, playbacks using synthetic advertisement calls have usually shown that some highly invariant, species-typical properties of conspecific calls are actually not used by receivers to select among signals. For example, in some species the dominant frequency is frequency modulated (changes from beginning to end), but females are just as attracted by synthetic calls lacking such modulation as by synthetic calls with modulation (**Figure 3**; Gerhardt, 1978b). Furthermore, many comparative studies have shown that a property may be relevant for one species but not for a closely related species (for review, see Gerhardt, 2001b). Such species differences are useful for comparative studies that aim to uncover general patterns of coevolution of signal production and recognition.

Patterns of Preference

In general, the preferred values of the relevant properties of advertisement calls may correspond well with the values typical of conspecific calls, or there may be a significant mismatch. In the first case, evolutionary biologists would characterize this pattern as a form of stabilizing selection. That is, males with calls having average values are more likely to attract mates than males with calls having values significantly below or above the average (**Figure 4A**). Stabilizing patterns of preference are often exerted on properties of the calls that are relatively invariant within and between males and that may contribute to species recognition (Gerhardt, 1991). Strong evidence that stabilizing patterns evolved to function in species isolation, however, requires showing differences in selectivity depending on whether other species with similar

Figure 3 Sonograms of a recorded and two synthetic calls of the gray tree frog, *Hyla versicolor*. The natural call (A) and one of the synthetic calls (B) have pulses that increase in frequency from beginning to end; the other synthetic call (C) has pulses of constant frequency. Females did not show a preference for natural or synthetic calls with frequency-modulated pulses to synthetic calls without modulation. Modified with permision from Gerhardt (1978b).

calls are present (e.g., Gerhardt, 1994; Höbel and Gerhardt, 2003). In the second case, the pattern would constitute directional selection. Females are likely to mate with males whose calls have properties higher or lower than the mean (Figure 4B). These patterns of preference indicate how values of the property are likely to change in the future unless there are other, negative consequences for a male producing calls with these attractive values. In the gray treefrog (*H. versicolor*), females prefer long-duration calls to short-duration calls, and females choosing to mate with long-calling males are likely to have offspring that grow faster and to a larger size than do females choosing to mate with short-calling males (Welch *et al.*, 1998). Call duration is also a reliable indicator of the metabolic costs of calling by males and hence may indicate a male's physical or genetic fitness (Wells and Taigen, 1986). In túngara frogs (*Physalaemus pustulosus*), calls that are attractive to females might also be especially detectable to predators (Ryan, 1985). In reality, frogs base mating and other decisions on variation in more than one acoustic property, and one study of the gray tree frog (*H. chrysoscelis*) showed that females weighed pulse rate (stabilizing preference function) more heavily than call duration (directional preference function) in areas where mating mistakes with a similar species were possible than in areas where such a species was absent (Gerhardt, 1994).

Neurobiologists have often studied mechanisms that lead to stabilizing selection and consider such processes to be some form of matched filtering (Capranica, 1965). As discussed later in this article, auditory organs are often tuned to the frequencies that are emphasized in conspecific calls, and neurons in higher auditory centers often respond best to sounds with temporal properties having values typical of conspecific calls. In contrast, little work has been done with mechanisms that might underlie directional selection, other than a few studies showing that the frequency tuning of the auditory organs or system as a whole does not exactly match the average frequency in male calls and a recent study, discussed later in this article, of 'counting' neurons.

Individual Recognition

Male bullfrogs (*R. catesbeiana*) defend territories for weeks or months; females usually lay their eggs in the territory of a male that they have chosen on the basis of his calls, his territory quality, or both. Fighting between males is intense in the early part of the breeding season, when territories are being staked out, but aggression between individual territorial neighbors soon wanes. Playback experiments have shown that males learn to recognize the calls of territorial neighbors and will habituate to the playback of a synthetic advertisement call. Playing back the calls of an unfamiliar male or a synthetic call with different properties than the habituating stimulus results in renewed aggression. This phenomenon has been termed the 'dear-enemy effect' and presumably has the benefit of allowing established rivals to save time and energy that might otherwise be used for unnecessary aggression. Playback experiments have also shown that males use spectral (frequency) properties of the call for neighbor–stranger discrimination and that this discrimination persists even when the playback is conducted at a different place around the perimeter of the male's territory, where aggressive responses to both sounds are elevated (Bee and Gerhardt, 2002). Statistical analyses have indicated that the minimal difference in spectral properties that result in elevated aggression are just above the usual within-male variation in these properties. Moreover, these properties vary sufficiently among males to allow for the discrimination of many pairs of neighbors and strangers.

Recognition of Acoustic Signals: Mechanisms

Auditory System

As in other animals, auditory receptors are hair cells. They are located in two distinct inner ear organs, the basilar papilla and the amphibian papilla, neither of

Figure 4 Preference functions based on variation in a single acoustic property. (A) A stabilizing function in which female reed frogs (*Hyperolius marmoratus*) preferred synthetic calls with dominant frequencies close to the mean in conspecific calls; the distribution of dominant frequency in a sample of males is shown in (C). (B) A directional function in which female reed frogs showed preferences for calls of high rate to calls of low rate. The distribution of call rate in a sample of males is shown in (D). Each line in (A) and (B) connects points showing the percentages of females choosing each of the two alternatives in a two-speaker choice test. Asterisks indicate statistically significant preferences (* < 0.05; ** < 0.01; *** < 0.001). Reproduced with permission from Gerhardt (2001a) in Dugatkin (ed.).

which is an obvious homologue of inner ear organs in higher vertebrates (Lewis and Narins, 1999). The amphibian papilla is the more complex of the two organs. It not only contains more hair cells but also shows some tonotopic organization, whereby hair cell receptors with similar tuning properties are located in close spatial proximity. The tuning of hair cells in the amphibian papilla is probably mediated by both mechanical and electrical processes; the latter are inferred from the fact that tuning is affected by anoxia and temperature. Finally, tone-on-tone inhibition occurs in the amphibian papilla, indicating a nonlinear interaction between receptors. This phenomenon involves the inhibition of a receptor's response to an excitatory tone by the addition of a second tone, usually of higher frequency. By comparison, the basilar papilla has fewer hair cells; these are tuned to a relatively narrow, though higher, range of frequencies than those that most effectively excite hair cells in the amphibian papilla. There is no evidence in this organ for tonotopy, temperature effects on tuning, or tone-on-tone inhibition. In most species of frogs and toads, the emphasized frequencies in advertisement calls match the sensitivity of one or the other or both of the inner ear organs (Figure 5; Gerhardt and Schwartz, 2001).

Auditory nerve fibers project from the inner ear organs to the dorsolateral nucleus, the first station in the ascending auditory pathway. At this level, there is already some convergence of neurons innervating the two papillae, but some separation of these low- and high-frequency channels is maintained at least to the level of the main midbrain auditory center, the torus semicircularis, which is a

Figure 5 Matched filtering in frogs and toads. The diagram shows the correlation between the sound frequency to which a species was most sensitive (lowest threshold) and the frequency or frequencies having the greatest relative amplitude in the conspecific advertisement call. Solid symbols = closed-field acoustic stimulation. Open symbols = free-field acoustic stimulation. Squares = low-frequency sensitivity of amphibian papilla. Triangles = high-frequency sensitivity of basilar papilla. The complete documentation of this figure (a key to the frog species from the data were plotted) is in Gerhardt and Schwartz (2001, Figure 1).

homologue of the inferior colliculus of higher vertebrates. There is at this level, however, little evidence for fine-scale tonotopy, such as that observed within the amphibian papilla. The torus semicircularis has several subnuclei and appears to be the main processing center for auditory information. Although the torus projects to higher-order cells in the thalamus and telencephalon, these brain areas do not appear to be necessary for either phonotaxis or selective responsiveness to biologically significant signals (Endepols *et al.*, 2003).

Some auditory nerve fibers and neurons in the ascending pathway synchronize fairly well to specific cycles of amplitude modulation in standard auditory stimuli (= amplitude-modulated sine waves or trains of short pulses) or in natural signals with a pulsatile structure. Synchronization for patterns typical of conspecific signals is not superior to that for patterns typical of heterospecific signals, provided repetition rates are below about 400 Hz. Selectivity for fine-scale patterns occurs in the torus semicircularis, where neurons with various filter properties have been described. Substantial proportions of one class of such neurons – bandpass – are best excited by repetition rates typical of conspecific calls in some, but not all, species of anurans that have been studied. A subset of bandpass neurons in leopard frogs and Pacific tree frogs has been found to respond only when a minimum number of pulses with the correct pulse rate occur (Alder and Rose, 1998).

Sound Localization

Higher vertebrates compare the magnitude of differences in time of arrival or intensity at the two ears in order to localize a sound source. The ears of most anurans are, however, too close together for such external differences to be usable. Most researchers think that instead, anurans use some form of pressure-difference mechanism, which has been well established for insects such as crickets and grasshoppers (see a review in Gerhardt and Huber, 2002). In such a system, the movement of the eardrum depends not only on its displacement from a sound wave arriving at its external surface but also on its displacement by sound waves arriving at its inner surface from internal pathways. The net displacement of the eardrum depends on the phase (timing) relationship of the two waves, which in turn depends on where the sound source is located. The nature of the pathways to the internal side of the eardrum and just how the inputs to its internal and external surfaces can generate directional cues in each eardrum are still unknown.

Reduction of Masking

Masking occurs when the signals of different individuals overlap in time, thus obscuring their detection and the resolution of temporal and spectral properties that are used for recognition. Frogs and toads that call in noisy choruses where masking is a severe problem probably use several mechanisms to compensate. First, the peripheral tuning of the auditory system to frequencies in conspecific calls can enhance detection of those calls, which will more effectively stimulate the auditory system than the calls of other species, which have different frequencies. Second, directional hearing results in the more efficient detection of sounds arriving from widely spaced sources than sounds arriving from sources situated adjacent to one another. This phenomenon contributes to the 'cocktail party effect,' whereby sound localization aids humans in eavesdropping on conversations in

different parts of a crowded, noisy space. Thus, males of the same species tend to maintain some minimal spacing even if they are not defending territories. Third, neighboring males of many species tend to time their calls so that they do not overlap those of their neighbors. If they do overlap, males compete to place their calls in a leading or lagging position, which makes them more detectable to females (see review in Gerhardt and Huber, 2002).

Fry, Dennis Butler (1907–1983)

J C Wells, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Dennis Fry was the leading British experimental phonetician of the third quarter of the 20th century. In 1934, after an early career as a teacher of modern languages, he was appointed Assistant Lecturer in the Phonetics Department of University College London (UCL), then the only university phonetics department in the UK and headed by Daniel Jones. Apart from the war years, which he spent in the acoustics laboratory of the RAF Central Medical Establishment, he remained at UCL throughout his career. He became Superintendent of its Phonetics Laboratory at the age of 30, and in 1949 succeeded Daniel Jones as Head of Department. He was appointed Professor of Experimental Phonetics in 1958. He gave up the headship of the department in 1971 and retired in 1975.

Despite some early work of a type more readily associated with the Daniel Jones school (Fry and Kostić, 1939), Fry's principal interest was experimental phonetics. His scientific career started in an era when the equipment of a modern phonetics laboratory included sensitive flames and mechanical kymographs. It culminated in the era of the minicomputer.

The 1940s and 1950s had seen the birth of information theory and of important developments in electronics, including the earliest electronic computers. Together with new signaling processing techniques such as the Vocoder, this led to a growth of interest in experimental phonetics. For the first time automatic recognition and synthesis of speech began to seem feasible. Fry, with a wide interdisciplinary knowledge and an awareness of linguistic aspects of speech not always shared by those educated solely in the scientific tradition, saw that an understanding of the speech process would involve not only acoustic aspects but also psychological, perceptual, and linguistic analysis.

He was the first to experiment with automatic speech recognizers using not only acoustic but also linguistic cues. To linguistic phoneticians, who tended to be naïve about the physical aspects of speech, Fry demonstrated the importance of laboratory experimentation. One of his best-known achievements was to demonstrate that stress in English words is perceived not mainly as a consequence of loudness (as American structuralists assumed) but of spectral (pitch) and temporal (duration) characteristics. To the experimentalists he insisted that – given the robustness of human speech perception under extremes of distortion and noise – communication could not be dependent solely on acoustic cues.

In 1958 he founded the scholarly journal *Language and Speech*, of which the Oct–Dec 1978 issue comprises essays in his honor and includes a list of his publications. From 1971 on he was President of the Permanent Council responsible for organizing the International Congresses of Phonetic Sciences.

Fry was an excellent singer and was involved in semi-professional singing throughout his life. In 1966 he became a governor of the Sadlers Wells Foundation.

One practical application of Fry's work was in relation to the hearing-impaired: his book *The deaf child* (with E. Whetnall), first published in 1964, is still in print.

Formal retirement did not mean that Fry stopped working. To the contrary, the books for which his name is most widely known were written after his retirement: *Homo loquens* (1977) and *The physics of speech* (1979).

Fujioka, Katsuji (1872–1935)

Y Nagashima, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Katsuji Fujioka was born in Kyoto, Japan, on August 12, 1872. He graduated from the Department of Hakugengaku (*Sprachenkunde*), College of Letters, Tokyo Imperial University, in 1897 and was admitted to further study in the graduate school. In 1901, he was ordered by the Japanese government, as was usual in those days, to study linguistics in Germany for three years. There he studied Indo-European linguistics and the history of linguistics, among other subjects. Upon his return from Germany, he was appointed Assistant Professor of Linguistics at Tokyo Imperial University in 1905 and Professor in 1910. He retired in 1933, and died on February 28, 1935, in Tokyo.

Fujioka's major field of interest spanned Europe and Asia. As a pioneer scholar in the development of linguistics in Japan, he lectured on such various themes as the outline of linguistics, general phonetics, Brugmann's *Kurze vergleichende Grammatik der indogermanischen Sprachen,* Streitberg's *Stand und Aufgaben der Sprachwissenschaft*, Paul's *Prinzipien der Sprachgeschichte*, Turkish–Mongolian–Chinese exercises, the historical grammar of Germanic languages, Ural–Altaic linguistics, Greek and Latin philology, and French and Romance linguistics. Among his pupils were such influential scholars in Japanese and other fields of linguistics as Shinkichi Hashimoto (Old Japanese and Japanese grammar), Shinpei Ogura (Korean linguistics and dialectology), Kyosuke Kindaichi (*see* **Kindaichi, Kyosuke (1882–1971)**), Kaku Jimbo (phonetics and theoretical linguistics), Sanki Ichikawa (English philology), and Shiro Hattori (*see* **Hattori, Shiro (1908–1995)**).

Fujioka's theory on the structural similarities among Uralic, Altaic, and Japanese languages has exerted considerable influence on the genealogical study of Japanese in Japan. He did not, however, believe in the genealogical relationship between Altaic and Japanese.

Among his scholarly works is an important Japanese translation of *Manbun roto* (*Man wen lao dang*, literally 'Manchurian-written old document'), its first translation into another language. This translation was published posthumously by Shiro Hattori (Fujioka, 1939). He published many translations of influential books, probably as preparation for his lectures, such as Bloomfield's *Introduction to the study of language,* Whitney's *The life and growth of language,* Saussure's *Cours de linguistique générale,* Gabelentz's *Die Sprachwissenschaft*, Paul's *Prinzipien der Sprachgeschichte*, and Meillet's *Introduction à l'étude comparative des langues indo-européennes*. A beautiful account of him as a scholar is to be found in Hattori's *Beginnings of linguistics* (privately printed, in Japanese).

Fujitani Nariakira (1738–1779)

N Harada, Advanced Telecommunications Research International, Kyoto, Japan

© 2006 Elsevier Ltd. All rights reserved.

Fujitani was born as the second son of Syundoo Minagawa, who was a doctor in Kyoto. Fujitani's brother, Kien Minagawa, was also a scholar, engaging in philology of Chinese classics. Fujitani succeeded to his father's property at the age of 19. He died young, at the age of 42, before his research came to be appreciated. Due to their high originality, Fujitani's works are now acknowledged as one of the leading contributions to the foundation of the study of Japanese grammar. In particular, Fujitani is regarded as one of the first traditional Japanese grammarians to propose a systematic classification of grammatical categories. Along with Norinaga Motoori, Fujitani is also considered as one of the founders of the modern study of *te-ni-o-ha* (noninflecting Case particles and postpositions) and verbal conjugation in Japanese. Around the time when Fujitani and Motoori actively engaged in research, the target of the study shifted to the *waka* poetry from the *Tyuuko* period (794–1185). This shift enabled the traditional linguists at the time to investigate a wider range of data, which brought a major change in the object of the study as well. Rather than focusing on *man'yoo gana* and glossaries of the *Zyoodai* period (710–794), concord, agreement, and contexts became the main research topics of the researchers. Fujitani's major works are '*Kazasi syoo*' (1767), 'Explaining *kazasi*,' '*Ayui syoo*' (1778), 'Explaining *ayui*,' and '*Yosoi-Zu*,' which is a draft of the chart of the verbal conjugation of Japanese.

In *Kazasi syoo* (1767), Fujitani proposed a classification of syntactic categories into the following three subclasses: (i) *kazasi* (literally 'accessories for hair and caps'), which includes heterogeneous pronominal elements, adverbial elements, conjunctive particles, emotive expressions, and prefixes, (ii) *yosoi* (literally 'costumes'), referring to predicates, and (iii) *ayui* (literally 'shoe strings'), covering Case particles, postpositions, auxiliary verbs, and suffixes. In *Ayui syoo* (1778), Fujitani further elaborated his three-way classification by including *na* ('name'; names and nominal elements) and expanding it into a four-class categorization. He then divided up *ayui* into two groups; the one that subcategorizes for nominal elements, and the other that subcategorizes for non-nominals.

The expanded four-way classification of Fujitani's is considered as having two origins; one is the classical study of *te-ni-o-ha* from the Tyuusei period (Middle Japanese; 1182–1603) and the other is his elder brother Kien Minagawa. In particular, the influence of his sibling is explicitly observed in Fujitani's analytical method and his emphasis on combinations (or subcategorization/selectional relations) of syntactic constituents. This contrasts Fujitani with two of his contemporary fellow Japanese grammarians, Motoori and Akira Suzuki (a disciple of Motoori's), who put more emphasis on concord and agreement relations among the syntactic constituents.

Due to being too innovative at the time, there was no successor to Fujitani's grammatical theory until the Meiji era (1868–1925), when Yoshio Yamada (1873–1958) took over Fujitani's research endeavor.

In particular, Fujitani is regarded as one of the first traditional Japanese grammarians to propose a systematic classification of grammatical categories. Along with Norinaga Motoori, Fujitani is also considered as one of the founders of the modern study of *te-ni-o-ha* (noninflecting Case particles and postpositions) and verbal conjugation in Japanese. Around the time when Fujitani and Motoori actively engaged in research, the target of the study shifted to the *waka* poetry from the *Tyuuko* period (794–1185). This shift enabled the traditional linguists at the time to investigate a wider range of data, which brought a major change in the object of the study as well. Rather than focusing on *man'yoo gana* and glossaries of the *Zyoodai* period (710–794), concord, agreement, and contexts became the main research topics of the researchers. Fujitani's major works are '*Kazasi syoo*' (1767), 'Explaining *kazasi*,' '*Ayui syoo*' (1778), 'Explaining *ayui*,' and '*Yosoi-Zu*,' which is a draft of the chart of the verbal conjugation of Japanese.

In *Kazasi syoo* (1767), Fujitani proposed a classification of syntactic categories into the following three subclasses: (i) *kazasi* (literally 'accessories for hair and caps'), which includes heterogeneous pronominal elements, adverbial elements, conjunctive particles, emotive expressions, and prefixes, (ii) *yosoi* (literally 'costumes'), referring to predicates, and (iii) *ayui* (literally 'shoe strings'), covering Case particles, postpositions, auxiliary verbs, and suffixes. In *Ayui syoo* (1778), Fujitani further elaborated his three-way classification by including *na* ('name'; names and nominal elements) and expanding it into a four-class categorization. He then divided up *ayui* into two groups; the one that subcategorizes for nominal elements, and the other that subcategorizes for non-nominals.

The expanded four-way classification of Fujitani's is considered as having two origins; one is the classical study of *te-ni-o-ha* from the Tyuusei period (Middle Japanese; 1182–1603) and the other is his elder brother Kien Minagawa. In particular, the influence of his sibling is explicitly observed in Fujitani's analytical method and his emphasis on combinations (or subcategorization/selectional relations) of syntactic constituents. This contrasts Fujitani with two of his contemporary fellow Japanese grammarians, Motoori and Akira Suzuki (a disciple of Motoori's), who put more emphasis on concord and agreement relations among the syntactic constituents.

Due to being too innovative at the time, there was no successor to Fujitani's grammatical theory until the Meiji era (1868–1925), when Yoshio Yamada (1873–1958) took over Fujitani's research endeavor.

Fulfulde

J O Breedveld, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The Language Name

Most Fulbe call their language Fulfulde. Other names currently used for the language are *Ful*, *Fula*, *Fulani*, *Peul,* and *Pulaar.* Fulfulde is in fact one large dialect continuum in Africa stretching over thousands of kilometers from Mauritania, Senegal, and Guinea in the west to as far as Sudan and Ethiopia in the east, and to Cameroon, the Central African Republic, and Congo in the south. The Fulbe call their own language *Pulaar* or *Pular* in the dialect areas of Fuuta Tooro (Senegal, Mauritania) and Fuuta Jaloo (Guinea, Sierra Leone) and *Fulfulde* in all the other dialect areas, such as Maasina (Mali), Liptaako (Burkina Faso), Gombe (Nigeria), and Aadamaawa (Cameroon). In English literature, *Fulani* is a name frequently used for both the people and their language; it is an English loanword from Hausa (spoken in Nigeria). In French literature, the people and the language are called *Peul,* which is a French loanword from Wolof (spoken in Senegal). In American literature, the name *Fula* is often used and is the name chosen for the language of the Fulbe by D.W. Arnott, who wrote an important reference book on this language. He argued that the term Fula "seems more appropriate as well as more euphonious than the plain stem *Ful*" (Arnott, 1970:1–2). The name *Ful* is often used in German; this name is based on the root, which is common to the name of the people (sing. *Pullo*, pl. *Fulɓe*) and the different authochtonous language names (*pular, pulaar, fulaare, fulfulde*).

The Language and Its Speakers

Fulfulde is an Atlantic language, its closest relatives are Wolof and Sereer (Serer). Atlantic is a subbranch of the Niger-Congo language family.

The number of Fulfulde speakers is unknown, because for good reasons population counts usually do not determine the different ethnic backgrounds of people in various countries. In addition, numerous people in several areas of West Africa speak Fula as a second language. In the *Ethnologue* (Grimes, 2003), the number of speakers is estimated to be between 13 and 17 million.

The Fulbe are known especially for two features: in West Africa, they are almost the only group that has specialized in cattle herding (cf. Blench, 1999), and they have played an important role in the spread of Islam in this part of the world (cf. Last, 1987). The importance of cattle for the Fulbe is reflected in the existence of a noun class NGE, which classifies all cow names and, depending on dialect, some other terms related to cows: These nouns are all pronominalized by the same pronoun *nge* (Breedveld, 1995a, 1995b). The involvement of the Fulbe with Islam is reflected in the language by numerous religious and other loanwords from Arabic (Labatut, 1984). In most areas, the class of learned Qur'anic teachers have their own sociolect that has incorporated a number of Arabic sounds (e.g., the velar fricative [x]).

Several Fulfulde key cultural words, such as *pulaaku* and *semteende,* have received a lot of attention in studies on Fulbe culture (cf. Stenning, 1959; Dupire, 1970; Riesman, 1977; Breedveld and De Bruijn, 1996). Often, these words are associated with a code of behavior. However, prescribed conduct in the Fulbe societies differs according to social class, and most descriptions take the highest social class – the *rimɓe* or so-called noblemen – as the standard for the whole society, thus over-generalizing rules of behavior in certain contexts to the whole Fulbe society. In Mali, certain terms describing behavior seen as typical for the Fulbe are loanwords from neighboring languages (e.g., *yaage* 'respect, restraint, avoidance behavior' is a loanword from Soninke). This borrowing indicates that some component of these ideas is defined regionally and not ethnically.

Orthography

The Fulfulde language is written in both Arabic and Latin script. In both scripts, special conventions exist for writing lengths of vowels and consonants and for writing the prenasalized and laryngealized consonants (Ladefoged, 1964; Breedveld, 1995a). There is disagreement on the phonetic nature of the latter; some claim that these consonants are implosive (Sylla, 1982; Lex, 1987) or pre-glottalized (Klingenheben, 1963; Swift *et al.,* 1965). In 1966, experts attending a UNESCO meeting for the 'Unification of Alphabets of the National Languages' recommended a unified orthography for the Fulfulde language as shown in Tables 1 and 2 (Arnott, 1970).

Table 1 Orthography of Fulfulde vowels (short/long)

	Front	*Back*
High	i/ii	u/uu
Mid	e/ee	o/oo
Low		a/aa

Recommended by UNESCO, 1966.

Different authors and ministries of education in different West African countries use the Fulfulde alphabet in different ways. For example in Senegal the symbol [ñ] is used instead of the digraph [ny] (e.g., Fagerberg-Diallo, 1983). Arnott (1970) has used the digraph [sh] for the phonetic symbol [ʃ] because that sound has replaced [c] in the Gombe dialect. Many authors describing the eastern Fulfulde dialect also use the letter [v] for a labiodental fricative that occurs in these dialects (Labatut, 1982; Mohamadou, 1991).

Noun Class System

All the nouns in Fulfulde are divided into groups with different grammatical markings. These groups are called 'noun classes,' and the number of noun classes varies according to dialect. For example, the Aadamaawa dialect spoken in eastern Nigeria and Cameroon has 25 classes, whereas the Maasina dialect spoken in Mali has 22. The noun classes group nouns according to semantic and formal grounds. Most nouns end in the suffix form of the noun class to which they belong. The reference marker or concord that is basically the same for all nouns of the same noun class occurs in all pronominalized forms of the noun (pronouns) and in all words that modify the noun (e.g., adjectives, demonstratives). In the following example from the Maasina dialect, Tioulenta (1986:6), writing a prize-winning novel about a young man leaving the village for the big city, used in one sentence repeatedly the concord KOY, which marks the plural diminutive. The concords reoccur with the forms *-oy*, *-woy*, and *-koy* in several pronominal and modifying words that refer to the nouns in the KOY-class.

Yogaaɓe	*mbittan*	*njoppa*	*ndew-oy*
some	will leave	leave behind	little women-KOY
naye-woy	*ngarbintoo-koy*		
old-KOY	begging-KOY		

Some will leave behind little old women begging

e	*ngor-oy*	*maw-koy*	*koy*	*mbaaworaa.*
and	little men-KOY	old-KOY	who	are powerless

and little old men who are powerless.

The allomorphy of the suffix forms (e.g., that which determines whether the form of the class suffix is *-oy*, *-woy*, or *-koy*) is still the subject of debate in Fulfulde studies (Klingenheben, 1941; Mohamadou, 1991; Paradis, 1992; Breedveld, 1995a; Gottschligg, 1997). The question of the semantic basis of the noun class system in Fulfulde has also recently received new attention (Mohamadou, 1991; Breedveld, 1995b). However, consensus has not been reached on these subjects.

Consonant Alternation

A large number of consonants in Fulfulde are subject to alternation in certain contexts. In most dialects, the verbal system shows a change in the initial consonant of the verb stem, depending on plural or singular number of the subject, and also when the pronominal pronoun follows rather than precedes the verb stem.

mi ***w****ar-ii*
I come-COMPLETIVE
I have come

ɓe ***ng****ar-ii*
I come-COMPLETIVE
I have come

mande ***ng****ar-ɗaa*
when come-you sg. COMPLETIVE
When have you come?

In nominal stems, the initial consonant can alternate among three categories: a basic (continuant or fricative) consonant (F), a plosive consonant (P), and a pre-nasalized consonant (N). Table 3 shows the consonants that alternate in nominal stems.

Table 2 Orthography of Fulfulde consonants (short/long)

	Labial	*Alveolar*	*Palatal*	*Velar*	*Glottal*
Plosive					
Voiceless	p/pp	t/tt	c/cc	k/kk	'/''
Voiced	b/bb	d/dd	j	g	
Laryngealized	ɓ/ɓɓ	ɗ/ɗɗ	y/yy		
Prenasalized	mb/mmb	nd/nnd	nj/nnj	ng/nng	
Nasal	m/mm	n/nn	ny/nny	ŋ/ŋŋ	
Continuant					
Fricative	f	s			h
Glide	w/ww		y/yy		
Rolled		r/rr			
Lateral		l/ll			

Recommended by UNESCO, 1966.

Table 3 Consonant alternation in Fulfulde

Basic (F)	*w*	*r*	*y*	*y*	*w*	*b*	*d*	*j*	*g*	*f*	*s*	*h*
Plosive (P)	b	d	j	g	g	b	d	j	g	p	t	k
Prenasalized (N)	mb	nd	nj	ng	ng	mb	nd	nj	ng	p	t	k

Basically, the articulatory nature of the first consonant of a nominal depends on the noun class suffix. This distribution is shown in the following nominal paradigms derived from the verb stem *yim-* 'to sing, recite':

- *yim-re* poem (NDE class suffix: F initial consonant)
- *jim-e* poems ('DE class suffix: P initial consonant)
- *jim-ol* (long) song (NGOL class suffix: P initial consonant)
- *jim-i* (long) songs ('DI class suffix: P initial consonant)
- *jim-el* small song, poem (NGEL class suffix: P initial consonant)
- ***nj**im-oy* small songs, poems (KOY class suffix: N initial consonant)
- *jim-al* big song, poem (NGAL class suffix: P initial consonant)
- *jim-eele* big songs, poems (DE class suffix: P initial consonant).

That the form of the initial consonant of nouns is determined by the class is a possible remnant of the fact that the classes that are now marked by suffixes were once prefixes (De Wolf, 1985).

There are dialect variations in the system of consonant alternations. For example, there is no initial consonant alternation in the verbal system in the dialects of Fuuta Jaloo. Additional consonants alternate in the nominal systems; for example, the dialect of Fuuta Tooro (Senegal) has an additional set '-g-ng, and in Aadamaawa (Nigeria, Cameroon), the additional consonant alternation set v-b-mb occurs.

Focus as a Salient Feature of Fulfulde Syntax and Verbal Morphology

Most literature devoted to Fulfulde syntax also deals with its complicated verbal morphology, because both the form of the verbal conjugation and word order are determined by focus (Labatut, 1982; McIntosh, 1984). For example, in a sentence without any of the constituents in focus, the marker of the incompletive verbal conjugation is *-an*. As soon as one of the constituents is in focus, the focused constituent is placed in the first position of the sentence and the so-called relative form of the incompletive *-ata* is then used to conjugate the verb.

Baaba *sood-**an*** *kaddule.*
father buy-INCOMPLETIVE clothes
Father will buy clothes.

Kaddule *baaba* *sood-**ata**.*
clothes father buy-RELATIVE.INCOMPLETIVE
CLOTHES father will buy.

There are three voices – active, middle, and passive – marked in the Fulfulde verb, which have ramifications for the verbal morphology and constituent order. The following three sentences show combinations of the verb stem *yeggit-* 'forget' and the negative incompletive conjugation in the three voices.

Mo *yeggit-**ataa*** *ndee innde.*
he forget-NEGATIVE INCOMPLETIVE that name
He will not forget that name.

Ndee *innde* *yeggit-**ataako**.*
that name forget-NEGATIVE INCOMPLETIVE MIDDLE VOICE
That name cannot be forgotten.

Ndee *innde* *yeggit-**ataake**.*
that name forget-NEGATIVE INCOMPLETIVE PASSIVE VOICE
That name will not be forgotten.

Sentences in the passive and middle voice usually have one constituent less than sentences in the active voice. There are three paradigms of conjugational verb suffixes: each voice had its own set.

Linguistic Taboos

Part of what Fulbe consider to be proper behavior is not to say what should not be said. Certain words are taboo for all speakers, and certain names and terms of address are taboo in particular (kinship) relations.

The taboo on body part nouns has led to much dialect variation in Fulfulde. In Malim, the euphemism for the back is *caggal*, and *ɓaawo* is considered rude. Conversely, *ɓaawo* is the proper word in Cameroon. Because prepositions are grammaticalized from some body part terms, the same dialectal variation is

replicated. In Mali, the preposition *nder* 'in' is not used, possibly because it is derived from the noun *reedu* 'belly', which is considered rude. In certain dialects, the noun class concord *ngu* is taboo because it is associated with the female genitals.

There are many taboos on names (Ameka and Breedveld, 2004). There is a general tendency to use clan names, rather than more personal first names. In certain specific kinship relations, names are replaced by other words (e.g., a child named after his or her grandmother is called *innere* 'little mother-thing').

Although many studies have been written on the Fulfulde language (cf. Seydou, 1977), descriptions of many dialects are lacking. The study of dialect comparison remains an important goal for further research.

Functional and Skopos Oriented Approaches to Translation

C Nord, Hochschule Magdeburg-Stendal, Magdeburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Functional translation theories are gaining ground in many parts of the world, especially where translation needs are pressing and equivalence theories are out of the question because of (1) different stages of (lexicological, terminological etc.) development in source and target languages, (2) discrepant levels of knowledge and experience in source and target audiences, or (3) large gaps between source and target cultures, value systems, perspectives, world views, and so on.

Nevertheless, criticisms have been leveled at the theoretical foundations and applicability of functionalist approaches in general and of skopos theory in particular. Although, as Toury pointed out with reference to both skopos theory and his own target-oriented approach, "target-orientedness as such no longer arouses the same antagonism it used to less than 20 years ago" (Toury, 1995: 25), quite a number of criticisms are still, explicitly or implicitly, present in debates on translation theory today. Some scholars keep maintaining the view that equivalence is the only valid yardstick of translation quality, as well as being a constitutive characteristic of translation proper (cf. Koller, 1995).

Is equivalence a safeguard against manipulation? Post-colonial translation studies show that the (theoretical) notion of equivalence has never stopped any translator (or commissioner of translations) from manipulating source texts consciously or unconsciously. A corrective is needed for both equivalence-based and function-oriented translation theories. For this purpose, I have suggested the concept of 'loyalty' (cf. Nord, 1997a) to account for the culture-specificity of translation concepts, setting an ethical limitation on the otherwise unlimited range of possible skopoi for the translation of one particular source text.

Historical Overview

Functional approaches to translation developed in Germany in the beginning of the 1980s. At that time, university programs for translation and interpreting could look back on quite a long tradition, since the first interpreter training had been established at Humboldt University in Berlin as early as 1894. During and shortly after World War II, translator training departments were founded at several universities in both East and West Germany to meet the increasing demand for well-trained translators and interpreters.

The training was mainly practical; theoretical foundations were borrowed from linguistics. Equivalence between source and target language was the quality yardstick that was never questioned, although the definitions of the concept were far from satisfactory. The material used in the classroom comprised mostly essays or literary texts used to train the students' linguistic and stylistic proficiency in both the source and the target language. Trainers were often language teachers with little or no experience in professional translation.

Employers, however, kept complaining about the poor competence of graduated translators with regard to the variety of text genres and tasks that had to be tackled in professional practice, where 'equivalence' of whatever kind is often neither possible nor desirable. For example, resumé translations need not give more than the gist of the source-text information, specialist research reports sometimes must be translated for a broader nonspecialist audience, and poorly written operating instructions have to be adapted to the needs of a target culture where technical or cultural conditions are completely different from those of the source culture. Teachers needed a new yardstick to explain why different contexts call for different translation solutions, and the pragmatic turn in linguistics seemed to point in the right direction.

The publication of Hans J. Vermeer's 'Framework for a general translation theory' (1978) seemed to offer a theoretical foundation for translator training. The theory was later explained in more detail in a book co-authored with Katharina Reiss, who had prepared the ground for a functional approach in her work on translation criticism as early as 1971 (cf. Reiss, 1971; Reiss & Vermeer, 1984). Using the Greek word *skopos*, meaning 'purpose' or 'aim', Vermeer called his theory skopos theory because he considered translation to be a type of human action. 'Action,' in turn, was defined as a behavior intended to change a state of affairs. In accordance with action theory (for example, von Wright, 1968), Vermeer defined translation as a purposeful behavior that takes place in a given situation; it is part of the situation at the same time as it modifies the situation. Further, because situations are embedded in cultures, any evaluation of a particular situation, of its verbalized and nonverbalized elements, depends on the status it has in a particular culture system (cf. Vermeer, 1989).

According to this line of thought, translation cannot be considered a one-to-one transfer between languages, and a translation theory cannot draw on a linguistic theory alone, however complex it may be.

Skopos theory is, therefore, a culture-oriented approach. One of the most important factors determining the purpose of a translation is the intended audience of the target text, specifically its culture-specific world knowledge, expectations, and communicative needs. Every translation is directed at an intended audience, because to translate means "to produce a text in a target setting for a target purpose and target addressees in target circumstances" (Vermeer, 1987: 29).

In the phrase just cited, the source text is not even mentioned. Its status is clearly much lower in skopos theory than in equivalence-based theories. Vermeer regarded a text as an 'offer of information,' from which any receiver picks precisely the items he or she wants, and is able, to process. Therefore, a translation is an offer of information produced in the target language and culture for target-culture addressees about another offer of information that was produced in a source language and culture for source-culture addressees. This means that, in the translation process, the translator's decisions are no longer guided by the linguistic and stylistic characteristics of the source text but by the constellation of participants and conditions of the communicative situation for which it is produced. Instead of equivalence between source and target texts, the aim is adequacy for the translation purpose.

Right from the outset, skopos theory had a considerable impact on the methodology of translator training. Hans G. Hönig and Paul Kußmaul (1982), both engaged in translator training, gave the starting signal with their book on translation strategy. They showed how functional strategies lead to appropriate solutions to translation problems. Although their examples are taken from German-English translating, the problems they discussed are clearly not language-specific, but may occur, with slight variations caused by language structures and culture conventions, in any translation situation. Other scholars followed suit, developing models for a functional approach to translation error analysis (Kupsch-Losereit, 1985), functional text analysis (Nord, 1988), functional text typology (Göpferich, 1995), translator training (Kußmaul, 1995), a functional typology of translations (Nord, 1997b), and a functional redefinition of the translation unit (Nord, 1997c). Applications of functionalist methodology dealt with the descriptions of nonverbal behaviour in the *Odyssey* (Vermeer, 1992), titles and headings (Nord, 1993, 1995), culture-references in literary texts (Nord, 1994), the cultural transfer in simultaneous interpreting (Pöchhacker, 1995), text-type conventions (Kußmaul, 1997), and the translation of paralanguage in literary texts (Nord, 1997a), to name only a few contributions available in English.

It is a feature common to the functionalist scholars engaged in translator training that they try to focus on the language-independent pragmatic and cultural aspects of translation, emphasizing the specific nature of translation competence, rather than language proficiency. Obviously, they want to distance themselves from the first phase of German translator training, which evolved from the philologies and from language teaching.

Fundamental Principles of Functional Translation

The main hypotheses of a functional approach to translation may be summarized in the following principles:

- The purpose of the translation determines the choice of translation method and strategy. This means that any choice among two or more available solutions to a translation problem must be guided by an intersubjective criterion that, in the functionalist framework, is provided by the communicative function or functions for which the target text is needed.
- The purpose is defined, either explicitly or implicitly, in the translation brief provided by the client or commissioner. The translator interprets the translation brief in order to find out what kind of translation is needed and which translation strategy to choose.
- A translation may be called functional if it 'works' for its receivers in a particular communicative situation precisely in the way the client wants it to work. The translator has, therefore, to evaluate the audience's capacities for comprehension and cooperation, especially with regard to previous knowledge about the topic, and anticipate the possible effects that certain forms of expression may have on the readership.
- Function is not an inherent quality of a text. It is attributed to the text by the receiver, at the moment of reception. It is the receiver who decides whether (and how) a text 'functions' (for him or her, in a specific situation). If, as we know, the same receiver at different moments of his or her life may react in different ways to the 'same' text (e.g., to Shakespeare's *Romeo and Juliet*), it is most improbable that different readers, at different moments, will react to the same text in the same way, let alone readers belonging to different cultural environments.
- Yet, if this is true, how can we be sure that a text achieves the function we want it to achieve? We cannot. Usually, we rely on the audience's

willingness to cooperate in a given situation; otherwise, communication would be impossible. Any text producer, therefore, consciously or unconsciously uses some kind of verbal and/or nonverbal 'function markers,' which indicate the intended communicative function(s). Thus, printing the text in tiny letters on a slip of paper that comes with a box of pills indicates patient information; imposing a title, such as 'Instructions for use,' is a most explicit function marker. Other types of markers might be a particular text format or layout, such as a newspaper headline; certain sentence structures, such as imperatives in a recipe; a particular register, like that of an editorial; certain forms of address for the readership, for example in a student's manual, and the like. If the receivers recognize the function markers, they may accept the text as serving the intended function. However, markers can only be interpreted correctly by a receiver who is familiar with the marker code used.

- Basically, the function (or set of functions) intended for, and/or achieved by, the target text may be different from that intended for, and/or achieved by, the source text.

Functionality and Loyalty

Looking at the basic principles presented above, we may wonder why there is no mention of such equivalence-based criteria as 'faithfulness' or 'fidelity' to the source text. This is the reason why some critics reproach functionalism for producing "mercenary experts, able to fight under the flag of any purpose able to pay them" (Pym, 1996: 338). This criticism refers to an ethical quality related to the status of the source text. If the linguistic and stylistic features of the source are no longer regarded as the yardstick for translation quality, does this mean that the translator is entitled to do whatever he or she likes?

Indeed, the first basic principle of functionalism could be paraphrased as 'the translation purpose justifies the translation procedures,' and this statement could easily be interpreted as 'the end justifies the means.' In this case, there would be no restrictions to the range of possible ends: The source text could be manipulated, as clients (or translators) saw fit. In a general theory, this doctrine might be acceptable enough, since one could always argue that general theories do not have to be directly applicable. Yet, translation practice does not take place in a void. It takes place in specific situations set in specific cultures, so any application of the general theory, either to practice or to training, has to take account of the specific cultural conditions under which a text is translated.

At different times and in different parts of the world, people have had and still have different concepts of the relationship that should hold between an original and the text that is called its translation. According to the prevailing concept of translation, readers might expect, for example, that the target text gives exactly the author's words; other cultures might want it to express the author's intention, even though this would mean changing the words. Still others could praise archaizing translations or ones that are comprehensible, readable texts. Taking account of all these different expectations, which may vary according to the text type in question or depend on the self-esteem of the receiving culture with regard to the source culture, the translator acts as a responsible mediator in the cooperation developing among the client, the target audience, and the source-text author. This does not mean that translators always have to do what the others expect – doing so may even be impossible if the three parties expect different translational behaviours. It just means that the translator has to anticipate any misunderstanding or communicative conflict that may occur due to discrepant translational concepts and has to find a way to avoid them.

This responsibility that translators have toward their partners can be called 'loyalty.' Loyalty is not the old fidelity in new clothes, because fidelity usually refers to an inter*textual* relationship holding between the source and the target texts as linguistic entities. However, loyalty is an inter*personal* category referring to a social relationship between individuals. In a general model, loyalty would be an empty slot that, in a specific translation task, is filled by the demands of the translation concepts of the cultures in question, especially when the source-text author and the target-text audience hold discrepant views of what a translator should or should not do. It is the translator's task to mediate between the two cultures, and mediation cannot mean the imposition of the concept of one culture on members of another.

The loyalty principle thus adds two important qualities to the functional approach. Because it obliges the translator to take account of the difference between culture-specific concepts of translation prevailing in the two cultures involved in the translation process, it turns skopos theory into an anti-universalist model, and because it induces the translator to respect the sender's individual communicative intentions, as far as they can be elicited, it reduces the prescriptiveness of 'radical' functionalism.

The first basic principle of functional translation theory mentioned above should, therefore, be complemented by the following limitation: The acceptability of translation purposes is limited by the translator's

responsibility with regard to her or his partners in the cooperative activity of translation. Loyalty may oblige translators to lay open their translation purposes and justify their translational decisions.

As the only one in the communicative 'game' of translation who knows both the source and the target cultures, the translator plays a powerful role. She could easily deceive her partners without anybody noticing – sometimes even just by 'faithfully' translating 'what the source text says.' Seen in this way, loyalty may be a corrective in the power play among client, author, target receivers, and the translator.

Functional Categories

T Parodi, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

In the generative framework (particularly in the principles and parameters framework, Chomsky, 1981) a distinction is drawn between substantive or lexical categories, such as N(oun), V(erb), A(djective), and P(reposition), on the one hand, and nonsubstantive or functional categories, such as C(omplementizer), T(ense), or D(eterminer), on the other. The distinction roughly corresponds to the traditional one between content and function words.

The contribution of lexical categories (e.g., 'tree', 'walk') is that of conveying substantive content. Functional categories, on the other hand, take on the task of conveying grammatical information about sentence type, finiteness, definiteness, among others. We can think of verbs as an example of a lexical category ('walk') and AGR(eement) or T(ense) as an example of functional categories ('has walked', 'walked').

Basic examples of functional categories are I(nflection), the locus of finiteness in the clause, with specifications for agreement and tense (see examples [1] and [2]) and C(omplementizer), which encodes information about discourse connections and the illocutionary force of the clause (± interrogative, see examples [3] and [4]). In a parallel way Abney (1987) first proposed D(eterminer) as a functional category in the nominal. In English this category would encode information about definiteness and be instantiated by articles, demonstratives, and other determiners (see [5]).

(1) Kim **has** bought apples
I [+AGR], [+TNS]

(2) Kim has promised **to** buy apples
I [–AGR], [-TNS]

(3) you know **that** Kim likes apples
C [−wh]

(4) **what** does Kim like?
C [+wh]

(5) **the/** some/ these apples
D

Given the differences between lexical and, functional categories, there is a division of labor between them. Lexical categories play a role in the interpretation of linguistic expressions, in conceptual aspects. Functional categories' main role, on the other hand, lies in computational aspects of linguistic structures.

Since Chomsky (1970), lexical categories and, later functional categories have been assumed to be feature complexes. Their feature specification differs in accordance with their role in linguistic expressions. Theta features are specific of lexical categories. A lexical category such as the verb *buy* selects a certain set of theta roles, namely an agent and a patient. On the other hand, a functional category such as T(ense), realized for example as the auxiliary *has*, subcategorizes for a certain syntactic category, namely a verb phrase (but not for any specific theta role). Functional categories at the I-level are carriers of information about person, number, tense, etc., known as phi features.

Increasing emphasis has been put on the importance of features in the phrase structure. The division of labor between lexical and functional categories and their respective feature specification is reflected in the way they project: lexical categories must discharge all the theta roles they assign. Functional categories, on the other hand, discharge their subcategorization feature on their complement, a maximal projection. They then take a further maximal projection for the purpose of agreement.

Some functional heads have agreement features and attract a maximal projection to their specifier position for the latter to have their agreement features licensed and, thus, become 'visible.' This is the case for the head I attracting a subject D(eterminer) P(hrase) to the specifier of the I(nflectional) P(hrase). In this sense, then, functional categories are triggers for syntactic movement, depending on their feature strength.

Feature Strength

The features of functional categories are assumed to be valued as either weak or strong. Feature strength is responsible for movement and has a correlate on distributional facts.

Consider, for example, the distribution of the finite verb with respect to the negation in examples (6) and (7) from English and French, respectively, or that of the verbs in the interrogative sentences in (8) from English and (9) from German.

(6a) Kim did not buy many apples
(6b) *Kim buys not apples

(7a) Kim n' a pas acheté
Kim NEG *-have.3*SING NEG *buy.*PART
beaucoup de pommes
*a lot of apple-*PL
'Kim did not buy many apples'

(7b) Kim n' achète pas de pommes
Kim NEG- *buy.3*SING NEG *of apple-*PL
'Kim does not buy apples'

In French, all finite verbs, i.e., both auxiliaries and main verbs, appear to the left of the negative element

pas; in English, on the other hand, main verbs cannot appear to the left of *not*, only modals, auxiliaries and *do* can. Similarly, only modals, auxiliaries, and *do* can appear to the left of the subject in so-called subject–auxiliary inversion. In German, on the other hand, both main verbs and auxiliaries appear to the left of the subject in interrogatives.

(8a) *buys Kim apples?
(8b) does Kim buy apples?
(8c) has Kim bought apples?

(9a) kauf-t Kim Äpfel?
buy-3SING.PRES Kim apple.PL
'does Kim buy apples?'
(9b) hat Kim Äpfel ge-kauf-t?
has Kim apple.PL buy-PART
'has Kim bought apples?'

These differences are explained as differences in structural movement triggered in turn by properties of functional categories, more specifically by their feature value. It is assumed that the value of I is strong in French, but weak in English. Strong I attracts all verbs, weak I only a subset of them. In the case of interrogatives, it is assumed that the C head is strong in German and weak in English. The effects on movement are parallel to those in the IP.

The difference between English and French in one case and between English and German in the other is reduced to the strong/weak contrast in feature value. Although the analysis captures the facts, it might look like a superfluous stipulation if all one wants to say is that main verbs in English do not precede either the negation in a negative clause or the subject in an interrogative clauses and that this is different in French or German. However, the strong/weak contrast accounts for the facts in other domains and in other languages, and thus achieves a higher generalization power.

Functional Categories and Parametrization

The idea of functional categories allowed a new perspective on crosslinguistic variation, restricted to the domain of functional categories in the lexicon.

Chomsky (1995) assumed for each language a computational system and a lexicon. In the principles and parameters framework, universal principles account for those aspects which apply to all languages. Language-specific choices are formulated in terms of parameters, a finite set of options as to how the principles apply. The next question, then, is what these options are and in which language component they are to be found. Following Jespersen's intuition about the syntax–morphology divide, Chomsky assumed that parameters are limited to the lexicon and, within it, to functional categories. This limited lexical variation is of a morphological nature (see Chomsky, 1995: Introduction).

The examples above illustrate parametrization of the functional categories I and C, on the verbal and clausal level respectively.

Functional Categories and Learning

Language-specific choices are formulated in terms of parameters, which account for learnability. Given that functional categories are the locus of parametrization and of the syntactic organization of the clause, they play a central role in theories of both L1 and L2 acquisition.

Early child utterances display obvious differences with adult language. It has been observed (Radford, 1990, among many others) that these differences are related to properties of functional categories, such as omission of complementizers, of finiteness markers, or of determiners. Consider the examples under (10)–(14).

(10) Papa have it (Eve, 18 months) (Guasti, 2003: 106)

(11) Eve gone (has) (Eve, 18 months) (Guasti, 2003: 106)

(12) dog barking (Bethan, 21 months) (Radford, 1990: 84)

(13) Wayne in garden (Daniel, 23 months) (Radford, 1990: 84)

(14) Daddy go? (Daniel, 23 months) (Radford, 1990: 123)

The verb in (10) is not marked for agreement with the subject. Those in (11) and (12), the only verbs in the utterance, are nonfinite forms. Finite verbs or auxiliaries are missing in (11), (12), (13), and (14). Determiners are missing in (12) ('dog') and (13) ('in garden'). The question in (14) lacks a wh-word: the assumed adult utterance would be 'where does Daddy go?' In other words, all these peculiarities can be analyzed as problems with the functional categories C, I, and D.

Debate on this problem, starting in the late 1980s, focused on the question whether the observed differences between initial acquisitional stages and adult grammar were due to the unavailability of functional categories (Radford, 1990) or to their underspecification (Hyams, 1992, 1996; Wexler, 1994), which would explain the nonobligatoriness of tense in matrix clauses.

Bilingual situations, especially early bilingual children, offer an opportunity of observing – and directly comparing – the emergence of different parametric settings and with them language-specific differences (see e.g., Meisel, 1990, 1994) Research from the late 1990s has focused on the optionality observed both in first and second language acquisition. This

optionality has been attributed to the developmental process from underspecified to fully specified functional categories in first language acquisition. In the case of second language acquisition, the discussion centers on the problems encountered by learners when faced with a language whose feature specification is different from their first language, or one in which a certain functional category is not instantiated. An example for the first case could be that of a speaker of French, a language with strong I, learning English, a language with weak I. An example for the second case could be that of a speaker of Chinese or Japanese, languages without articles and which have been assumed not to have the category D, learning English, which does have articles (see e.g., White, 2003).

Functional Discourse Grammar

K Hengeveld, University of Amsterdam, Amsterdam, The Netherlands

J L Mackenzie, Lisbon, Portugal

© 2006 Elsevier Ltd. All rights reserved.

Functional Discourse Grammar is a functional-typological approach to language that (a) has a top-down organization; (b) takes acts in discourse rather than sentences as the basic units of analysis; (c) analyzes discourse acts in terms of independent pragmatic, semantic, morphosyntactic, and phonological modules, which interact to produce the appropriate linguistic forms; and (d) is systematically linked to a conceptual, a contextual, and an output component. A summary of the various properties of this model can be found in Hengeveld (in press); a full presentation of the model is given in Hengeveld and Mackenzie (in press).

A Functional-Typological Approach to Language

Functional Discourse Grammar (FDG) is the successor to Functional Grammar (FG; Dik, 1997a, 1997b), a theory of the organization of natural languages developed by Simon C. Dik and his colleagues since the late 1970s. FDG retains the strengths of FG, in particular by combining typological neutrality with formal rigor; at the same time FDG expands the scope

Figure 1 General layout of FDG.

of FG by taking the pragmatic and psychological adequacy of the theory very seriously, adopting as its starting point the communicator's intention to influence his or her interlocutor through the use of linguistic discourse. These notions impose extralinguistic explanatory constraints on the theory: an FDG will succeed to the extent that it clarifies the relation between the instrumentality of the language system in creating and maintaining communicative relationships (pragmatic adequacy) and to the extent that it obeys general cognitive restrictions on the production and interpretation of discourse (psychological adequacy). FDG occupies a position halfway between radically functional and radically formal approaches to grammar. In Butler's (2003) terms, it is a structural-functional grammar.

Linguistic typology, the study of the principles underlying formal variation across the languages of the world, is an essential source of inspiration for FDG, since the theory aims at developing a framework for the systematic description of all possible human languages. At the same time, FDG offers a coherent theoretical framework for typological work that goes beyond the 'basic linguistic theory' to which many typologists ascribe (Dryer, in press). Most importantly, the distinction between the different components of FDG forces the typologist to study the pragmatic and semantic typology of languages systematically, and not merely their syntactic and morphological typology.

Despite the centrality of discourse notions, FDG is not a discourse-analytical but a grammatical model: it captures the formal properties of linguistic units in terms of the world these properties are used to describe and the communicative intentions with which they are produced. This is precisely why FDG can be called a functional model of language.

General Overview

FDG is the grammatical component of a wider theory of verbal interaction. Where linguistic structure is determined by verbal interaction, this is captured as interaction between the grammatical component and a conceptual, a contextual, and an output component (see Figure 1). Within the grammatical component itself, ovals contain operations, boxes contain primitives (the basic building blocks used in operations), and rectangles contain the levels of representation produced by operations. In line with the top-down organization of FDG, we start our discussion of Figure 1 at the top.

At the prelinguistic conceptual level, a communicative intention (e.g., issuing a warning) and the corresponding mental representation (e.g., of the event causing danger) are relevant. The operation

Figure 2 The grammatical component of FDG.

of formulation converts these into interpersonal (pragmatic) and representational (semantic) representations. These in turn are translated into morphosyntactic and phonological representations through the operation of encoding. Just like the rules used in encoding, those used in formulation are language-specific, i.e., FDG does not presuppose the existence of any universal pragmatic or semantic notions. As a result, similar conceptual representations may receive different interpersonal and representational representations across languages, e.g., warnings are in some languages formulated as a distinct type of speech act, whereas in others they receive the same treatment as orders (see 'The Representational Level' below).

The output of the grammar is input to the operation of articulation, which, in the case of an acoustic output, contains the phonological rules necessary for an adequate phonetic utterance. Each level of representation within the grammar furthermore feeds into the contextual component, enabling subsequent reference to the various kinds of entity relevant at each level as soon as they are introduced into the discourse. The formulator draws on this component, so that the availability of antecedents and visible referents may influence the composition of (subsequent) discourse acts.

Figure 2 gives a more elaborate representation of the grammatical component as such. It shows the presence of four different levels of linguistic organization: the interpersonal, the representational, the morphosyntactic, and the phonological, which will be discussed one by one in the following sections. It also specifies the various sets of primitives feeding the operations of formulation and of morphosyntactic and phonological encoding, which we will discuss here.

The set of primitives relevant for formulation consists, firstly, of frames which define the possible combinations of elements at the interpersonal and representational levels for a certain language. Secondly, this set of primitives contains lexemes. In the implementation of the grammar, frames are selected first, and then lexemes are inserted into these. This reflects the options available to the speaker to describe one and the same entity through a variety of lexemes with different connotations and/or denotations. Thirdly, this set of primitives contains primary operators, which symbolize those pragmatic and semantic distinctions grammaticalized in the language under description (e.g., identifiability or evidentiality).

Morphosyntactic encoding makes use, first of all, of a set of templates for words, phrases, clauses, and sentences, and possibly larger units such as paragraphs. The primitives available for this operation also include all free grammatical morphemes. These have to be introduced at the structural level, since they occupy slots in the syntactic configuration, which is determined at this level. The third set of primitives relevant at the morphosyntactic level

consists of (morphosyntactic) secondary operators. These anticipate morphological means of expression, the form of which will eventually be selected at the phonological level.

The primitives used in phonological encoding consist, firstly, of a set of prosodic patterns, which organize the linguistic information coming in from higher levels into coherent blocks. The second set of primitives consists of bound grammatical morphemes that correspond to the primary or secondary operators specified at the higher levels of organization. Bound grammatical morphemes are introduced at the phonological level since in many languages the form of grammatical morphemes may be affected by the syntactic configuration in which they occur. A third set of primitives potentially relevant at the phonological level consists of (phonological) secondary operators. These anticipate acoustic (signed, orthographic) means of expression that are not a direct reflection of a primary operator, as when phonological phrasing is sensitive to the syntactic organization of a linguistic unit.

There are systematic correspondences across the three sets of primitives. Within each set there is a subset of units with a structuring function: the frames used in formulation, the templates in morphosyntactic encoding, and the prosodic patterns used in phonological encoding all serve the purpose of providing an overall structure for their respective levels. Within each set there is, furthermore, a subset of units in phonemic form: the lexemes used in formulation, the free grammatical morphemes used in morphosyntactic encoding, and the bound grammatical morphemes used in phonological encoding all contribute to the cumulative segmental specification of the underlying representations. Finally, within each set of primitives there is a subset of operators: primary operators are relevant to the operation of formulation, secondary operators to the operation of encoding.

The various levels of linguistic organization are all hierarchical in nature and are displayed as a layered structure. In its maximal form, the general structure of layers within levels is as follows:

(1) $(\pi\ \alpha_1\text{: [(complex) head]}\ (\alpha_1)\text{: } \sigma\ (\alpha_1))_\varphi$

Here α_1 represents the variable of the relevant layers, which is restricted by a possibly complex head and further restricted by one or more optional modifiers σ and/or is further specified by an operator π and/or a function φ. Modifiers represent lexical strategies, operators and functions grammatical strategies. The difference between the latter two is that functions are relational while operators are not.

The Interpersonal Level

The interpersonal level accounts for all the formal aspects of a linguistic unit that reflect its role in the interaction between speaker and addressee. The purposiveness of interaction entails that each speaker will employ a strategy, more or less consciously, to attain his or her communicative aims. The formulator employs the interpersonal level to indicate how this strategy is realized, with regard to both the speaker's purposes and to the addressee's likely current state of mind. The units of discourse through which the interpersonal level operates are organized hierarchically, in keeping with the global architecture of FDG, as follows (for ease of reading, the hierarchical structure has been indicated by indentation):

(2) $(\Pi\ M_1\text{: [}$	Move
$(\Pi\ A_1\text{: [}$	Act
$(\Pi\ F_1\text{: ILL } (F_1)\text{: } \Sigma\ (F_1))_\Phi$	Speech occurrence
$(\Pi\ P_1\text{: } \ldots\ (P_1)\text{: } \Sigma\ (P_1))_\Phi$	Speaker
$(\Pi\ P_2\text{: } \ldots\ (P_2)\text{: } \Sigma\ (P_2))_\Phi$	Addressee
$(\Pi\ C_1\text{: [}$	Communicated Content
$(\Pi\ T_I\ [\ldots]\ (T_I)\text{: } \Sigma\ (T_I))_\Phi$	Subact of Ascription
$(\Pi\ R_I\ [\ldots]\ (R_I)\text{: } \Sigma\ (R_I))_\Phi$	Subact of Reference
$\text{] } (C_1)\text{: } \Sigma\ (C_1))_\Phi$	Communicated Content
$\text{] } (A_1)\text{: } \Sigma\ (A_1))_\Phi$	Act
$\text{] } (M_1)\text{: } \Sigma\ (M_1))_\Phi$	Move

The highest layer in this hierarchy, the Move, describes the entire segment of discourse under analysis, with the various lower layers containing components of that segment. The hierarchy also represents the sequencing of linguistic actions: a Move may consist of several temporally ordered Acts; an Act may contain several temporally ordered Communicated Contents, and they in turn may contain multiple Subacts of Ascription and or Reference. To give a simple example, the positioning of an Act before or after a strategically more central Act determines whether it is understood as an Orientation – as in the first element of (3a) – or as an Afterthought – as in the last element of (3b):

(3a) Football, I don't really like it.
(3b) I don't really like it, football.

In conversations, Moves are contributions that either call for a reaction from the addressee or are themselves a reaction. The Move does not correspond exactly to any grammatically identifiable unit of discourse, but its status as Initiation or Reaction does impinge upon its form (e.g., its intonational contour). Moves are composed of one or more Acts of discourse (A_1, A_2, ...), which make up the Head of the Move. An example of a Move containing two Acts is (4):

(4) Watch out, because there may be trick questions in the exam.

The first Act issues a warning through an Imperative Illocution; the second, subsidiary Act provides a Motivation for the warning (signaled by the subordinator *because*).

FDG takes the Act rather than the clause to be the basic unit of analysis in grammatical theory. This is because there is at best a default correlation between Acts and clauses. A speaker will generally not express more of his or her communicative intention than is required to understand it; correspondingly, the analysis of a particular Act in FDG will show only those components that have actually been deployed by the speaker, reflecting the actional nature of this level. In this way, it can be explained, for example, why the Turkish interrogative particle *mI* (which displays vowel harmony) can be attached to structural units of any type: a clause, as in (5a); an NP, as in (5b); or an interjection, as in (5c):

(5a) Ahmet sinema-ya git-ti mi?
Ahmet cinema-DAT go-PAST INTER
'Did Ahmet go to the movies?' (Kornfilt, 1997: 5)

(5b) Bugün mü?
today INTER
'Today?' (Lewis, 1967: 105)

(5c) Tamam mi?
OK INTER
'OK?'

In the construction of an Act, the formulator chooses from three possible frames:

(6a) $(A_1\text{: } [(F_1)\ (P_1)_S\ (P_2)_A\ (C_1)]\ (A_1))_\Phi$ (Illocutives)
(6b) $(A_1\text{: } [(F_1)\ (P_1)_S\ (P_2)_A]\ (A_1))_\Phi$ (Interpellatives, Interactives)
(6c) $(A_1\text{: } [(F_1)\ (P_1)_S]\ (A_1))_\Phi$ (Expressives)

Where a Communicated Content ($\mathbf{C_1}$) is present, the Act belongs to the class of Illocutives. The familiar distinction between explicit and implicit performatives is reflected in the formulator's choice between assigning a lexical or an abstract predicate to the Head of the Speech occurrence ($\mathbf{F_1}$). Thus in (7a), the Head is the verb *promise* but in (7b) the abstract predicate DECL, as shown in the representations in (8):

(7a) I promise to do the washing-up.
(7b) I will do the washing-up.

(8a) $(A_I\text{: } [(F_I\text{: promise}_V\ (F_I))\ (P_I)_S\ (P_J)_A\ (C_I)]\ (A_I))_\Phi$
(8b) $(A_I\text{: } [(F_I\text{: DECL}\ (F_I))\ (P_I)_S\ (P_J)_A\ (C_I)]\ (A_I))_\Phi$

In keeping with the principles of FDG, no more abstract illocutionary primitives will be posited for each language than are justified by the grammatical distinctions present in that language. The primitives from which the world's languages make a selection appear to contain at least those in Table 1.

Table 1 Illocutionary primitives

DECLarative
INTERrogative
IMPERative
PROHibitive
OPTATive
HORTative
IMPRecative
ADMOnitive
CAUTionary
COMMissive

An illocutionary predicate, be it lexical (9a) or abstract (9b), can be specified by a Modifier $\mathbf{\Sigma^F}$ ($\mathbf{F_1}$), such as the adverb *sincerely*:

(9a) Sincerely, this is not a trick.
(9b) I promise you sincerely that this is not a trick.

(10a) $(A_I\text{: } [(F_I\text{: DECL}\ (F_I)\text{: sincerely}_{Adv}\ (F_I))\ (P_I)_S\ (P_J)_A\ (C_I)]\ (A_I))$
(10b) $(A_I\text{: } [(F_I\text{: promise}_V\ (F_I)\text{: sincerely}_{Adv}\ (F_I))\ (P_I)_S\ (P_J)_A\ (C_I)]\ (A_I))$

Where the specification of the illocutionary predicate is grammatical rather than lexical, it is analyzed in FDG as an operator $\mathbf{\Pi^F}$. These operators account for grammatical reinforcement and mitigation of the illocution. Modifiers and operators have been identified for all the units recognized within the interpersonal level.

The Communicated Content ($\mathbf{C_1}$) contains everything the Speaker wishes to evoke in his or her communication with the Addressee. Each Communicated Content contains one or more Subacts, so-called because they are forms of communicative action hierarchically subordinate to Acts. Subacts come in exactly two types. A Subact of Ascription ($\mathbf{T_1}$) reflects an attempt by the Speaker to evoke a property, while a Subact of Reference ($\mathbf{R_1}$) is an attempt by the Speaker to evoke a referent, i.e., a null, singleton, or multiple set of entities or qualities. Evocation is thus a cover term for the actions of reference and ascription.

It is to these Subacts that pragmatic functions such as Topic and Focus are assigned. Every Communicated Content, no matter how brief, will have a Focused Subact, i.e., one that is communicatively salient. The Focus status will be reflected in the encoding of the Subact at the morphosyntactic and/or phonological levels. Communicative salience can be attributed to three different factors: the speaker's strategic selection of new information (New Focus); the speaker's desire that the addressee should attend particularly to a Subact (Emphatic Focus); the speaker's desire to bring out the particular differences and

Table 2 Semantic categories

Semantic category	*Variable*	*Examples*
Individual	X	chair, brother_of
State-of-affairs	e	meeting, cause_of
Propositional content	p	idea, belief_in
Property/relation	f	color, fond_of
Location	l	garden, top_of
Time	T	week, end_of

Table 3 Word formation strategies and semantic categories

Semantic category	*Examples*
f	mean-**ness**, kind-**ness**, false-**ness**
x	writ-**er**, employ-**er**, sing-**er**
e	explora-**tion**, deci-**sion**, deple-**tion**
p	hope-**Ø**, wish-**Ø**, belief-**Ø**
l	brew-**ery**, bak-**ery**
t	summer-**time**, day-**time**

similarities between two or more Communicated Contents (Contrastive Focus). Not all Communicated Contents will have a Topic, however: in minimal or holophrastic utterances, for example, the one Subact will necessarily bear Focus.

A final example will give an impression of the operation of the interpersonal level. The Move (11) will be analyzed as (12), in which an Interpellative Act is followed by an Illocutive Act:

(11) Hey, you dropped your wallet!

(12) $(M_I\text{: } [$
$\quad (A_I\text{: } [(F_I\text{: hey } (F_I))\ (P_I)_S\ (P_J)_A]\ (A_I))$
$\quad (A_J\text{: } [(F_J\text{: DECL } (F_J))\ (P_I)_S\ (P_J)_A\ (C_I\text{: } [(R_I)$
$\qquad (T_I)\ (R_J)]\ (C_I))]\ (A_J)$
$] \ (M_I))$

The Representational Level

The representational level accounts for all the formal aspects of a linguistic unit that reflect its role in establishing a relationship with the real or imagined world it describes, i.e., it concerns designation rather than evocation, the latter being the job of the interpersonal level. The representational level thus takes care of the semantics of a linguistic unit. The semantic units through which the representational level operates are organized hierarchically, in keeping with the global architecture of FDG, as follows:

(13) $(\pi\ p_1\text{: } [$ — propositional content
$\quad (\pi\ e_1\text{: } [$ — state-of-affairs
$\qquad (\pi\ f_1\text{: } \ldots (f_1)\text{: } \sigma\ (f_1))_\varphi$ — property
$\qquad (\pi\ x_1\text{: } \ldots (x_1)\text{: } \sigma\ (x_1))_\varphi$ — individual
$\qquad (\pi\ l_2\text{: } \ldots (p_2)\text{: } \sigma\ (p_2))_\varphi$ — location
$\qquad (\pi\ t_1\text{: } \ldots (t_i)\text{: } \sigma\ (t_i))_\varphi$ — time
$\quad] \ (e_1)\text{: } \sigma\ (e_1))_\varphi$ — state-of-affairs
$] \ (p_1)\text{: } \sigma\ (p_1))_\varphi$ — propositional content

The differences between units at this level may be made in terms of the ontological category designated. To the extent that ontological categories are reflected in the language system, they have the status of semantic categories, each of which is provided with its own variable.

The most frequently encountered semantic categories can be defined taking Lyons (1977: 442–447) as the starting point. Using a terminology different from Lyons's, three semantic categories can be distinguished: individuals, states-of-affairs, and propositional contents. An individual can be located in space and can be evaluated in terms of its existence. A state-of-affairs can be located in space and time and can be evaluated in terms of its reality. A propositional content, being an exclusively mental construct, can be located in neither space nor time. It can be evaluated in terms of its truth.

To these three basic semantic categories three others may be added: properties, locations, and times. Properties (see Hengeveld, 1992; Keizer, 1992) have no independent existence and can only be evaluated in terms of their applicability, either to members of other semantic categories or to the state-of-affairs they describe in general. Thus, the property 'green' applies to individuals, the property 'recent' to states-of-affairs, and the property 'undeniable' to propositional contents. Similarly, the concepts of space and time cannot be reduced to any of the primary semantic categories, but rather specify dimensions of members of those semantic categories and therefore constitute independent semantic categories themselves. This point has been argued in Mackenzie (1992) for location and Olbertz (1998) for time. The various semantic categories are listed and illustrated in Table 2.

Various phenomena in the grammars of individual languages can be understood in terms of the semantic categories designated. Consider the examples in Table 3 of word-formation strategies in English. These examples show that, although there are exceptions, there is a clear relation between the form of this process on the one hand, and the semantic category designated on the other.

The description of an entity type α_1 may take various forms. It may be described through a construction with a lexical head (14) or through a construction with a complex head, consisting of a combination of (other) semantic categories (15).

(14) $(\pi\ \alpha_1\text{: } (f_1\text{: Lex } (f_1)_\varphi)\ (\alpha_1)_\varphi)$

(15) $(\pi\ \alpha_1\text{: } [(\alpha_2)_\varphi \ldots (\alpha_n)_\varphi]\ (\alpha_1)_\varphi)$

Some specific instantiations of these general schemas are given in (16) and (17):

(16) $(1\ x_i\text{: } (f_i\text{: } boy_N\ (f_i)_\varphi)\ (x_i)_\varphi)$
'a boy'

(17) $(\text{Past } e_i\text{: } [(f_i\text{: } read_V\ (f_i))\ (1\ x_i\text{: } boy_N\ (x_i))_{Ag}$
$(1\ x_j\text{: } book_n\ (x_j))_{Pat}]\ (e_i))$
'The boy read the book.'

In (16), a noun, itself designating a property (f_i), gives a simple lexical description of an individual (x_i). In (17), a combination of semantic categories, between brackets, gives a compositional description of a state-of-affairs. The combinations of semantic categories allowed in a language, both in quantitative and in qualitative terms, are specified in terms of representational frames, which form part of the set of primitives that feeds the formulator.

Quantitative restrictions on representational frames in languages may determine the minimum number of arguments required or the maximum number of arguments allowed. Thus, in some languages, such as Turkish, zero-place predicates do not exist, i.e., the minimum valency is one, whereas in other languages, such as Negerhollands, the maximum valency is two and alternative strategies have to be invoked to introduce additional participants, such as serialization. Qualitative restrictions on representational frames concern first of all the semantic categories of the component units, as when a language does not allow a propositional content to occur as an argument of a matrix verb, but requires a paratactic strategy instead. A second type of qualitative restriction concerns the way the relations between the component units of a frame are expressed, in terms of their semantic functions.

Here we will only illustrate the latter type of restriction. In English, a distinction is made between the locative relations *at*, *to*, and *from*, expressing Stative Location, Direction, and Source, respectively. In Tariana (Aikhenvald, 2003: 148), all three relations are expressed by the same case-suffix *-se*. These different ways of dividing the locative domain are captured through differences in the predication frames available for these languages. In Tariana, predication frames contain the general semantic function Location, as illustrated in (18):

(18) $(\pi\ e_1\text{: } [(f_1)\ (x_1)_{Ag}\ (l_1)_{Loc}]\ (e_1))$

English predication frames contain the more specific functions Stative Location, Direction, and Source:

(19a) $(\pi\ e_1\text{: } [(f_1)\ (x_1)_{Ag}\ (l_1)_{StLoc}]\ (e_1))$
(19b) $(\pi\ e_1\text{: } [(f_1)\ (x_1)_{Ag}\ (l_1)_{Dir}]\ (e_1))$
(19c) $(\pi\ e_1\text{: } [(f_1)\ (x_1)_{Ag}\ (l_1)_{So}]\ (e_1))$

Although predication frames are language-specific, the expectation is that important typological generalizations can be made in the form of implicational statements.

The nature of an entity type and the way its description is built up are not indicative of how the linguistic unit representing that entity is used within a discourse act. Entity types are categories, not functions. The functional analysis is given at the interpersonal level. Thus, the same property (f) may be either ascribed (T) to an entity, or it may be referred to (R). The following examples illustrate this point:

(20a) The teacher is **tall**.
(Ascription of zero-order entity: T/f)
(20b) **Tallness** impresses the teacher.
(Reference to zero-order entity: R/f)

(21a) Sheila is **a friend of mine**.
(Ascription of first-order entity: T/x)
(21b) **A friend of mine** visited me last night.
(Reference to first-order entity: R/x)

A more elaborate representation of (20) is given in (22):

(22a) $(C_I\text{: } [\ T_I \quad R_I \quad]\ (C_I))$
$(p_i\text{: } (e_i\text{: } [\ (f_i\text{: } \mathbf{tall}_A\ (f_i)) \quad (x_i\text{: } teacher_N\ (x_i))_\varnothing \quad]\ (ei))\ (p_i))$
(22b) $(C_I\text{: } [\ T_I \quad R_I\ R_I \quad]\ (C_I))$
$(p_i\text{: } (e_i\text{: } [\ (f_i\text{: } impress_V\ (f_i)) \quad (f_i\text{: } \mathbf{tall}_A\ (f_i))_{Ag} \quad]\ (e_i))\ (p_i))$
$(x_i\text{: } teacher_N\ (x_i))_{Exp}$

Examples such as these show that, though there are regular correspondences between the interpersonal and the representational levels, the two are basically independent of each other, allowing for a wide variety of interactions between them.

The Morphosyntactic Level

The morphosyntactic level accounts for all the linear properties of a linguistic unit, both with respect to the structure of sentences, clauses, and phrases, and with respect to the internal structure of complex words. The set of primitives used in morphosyntactic encoding provides the appropriate templates on the basis of which the morphosyntactic level is structured. Like other levels, the syntactic level and the templates it uses are hierarchically organized. It uses bracketed structures and category labels to capture the relevant formal properties of linguistic units within the language concerned, as in the following example:

(23) The girl danced beautifully.

$[$	Sentence
$[$	Clause
$[\text{the}_{Art}\ \text{girl}_N\text{-SG}]_{NPi}$	Noun Phrase
$[\text{dance}_V\text{-PAST}\ [\text{beautifully}_{Adv}]_{AdvP1}]_{VPi}$	Verb Phrase
$]_{CLi}$	Clause
$]_{Si}$	Sentence

As this example shows, the morphosyntactic representation captures the constituent structure of the

sentence as well as the internal ordering of elements within words. Thus, there are secondary operators serving as place-holders for the expression of singularity (SG) and past tense (PAST), which will receive their final phonemic expression at the phonological level.

Given the functional orientation of FDG, the expectation is that often the ordering properties of languages can be explained in terms of the meaning and use of linguistic units. The fact, however, that many other ordering properties are governed by independent principles warrants the postulation of a separate morphosyntactic level within the grammar, rather than as the output of the grammar as in FG. Further motivation for the presence of this level within the grammar is the fact that anaphoric reference can be made to morphosyntactic units, as in the following reaction to (23):

(24) **That**'s not what I would call **it**.

In this example *that* refers to the morphosyntactic syntactic unit selected for description (here $AdvP_i$), whereas *it* refers to the property described by that syntactic unit, which is represented at the representational level by means of an f-variable. By providing morphosyntactic constituents with an index, anaphoric reference can be established with each of them.

The existence of independent interpersonal, representational, and morphosyntactic levels within FDG is particularly useful when there is a discrepancy between them, i.e., in those cases in which morphosyntax does not mirror the semantic representation directly. A case in point is the phenomenon known as 'raising,' as in the following examples:

(25a) It seems that Sheila has arrived.
(25b) Sheila seems to have arrived.

'Raising' is functionally motivated, since the information structure of the discourse act as represented at the interpersonal level is decisive: in (25a) the constituent Sheila is part of the new information, in (25b) it is not. This factor is used in FDG to trigger the selection of the appropriate syntactic template, in which the Subject of the embedded clause in (25a) is treated as the Subject of the main clause in (25b) when provided with the pragmatic function Topic at the interpersonal level. At the same time, the semantic units underlying the embedded clause in (25a) has to be broken up, in the sense that elements logically belonging together end up in different places in order to meet the requirements of the interpersonal level. This is indicated in (26a) and (26b), which show the correspondences of the syntactic units involved in (24a) and (24b) with interpersonal and representational units.

(26a) $(C_I$: [(T_I) $(R_I$: [$(R_J)_{FOC}$ $(T_J)_{FOC}$] $(R_I))$] $(C_I))$
$(p_i$: [(f_i) $(p_j$: [(x_i) (f_j)] $(p_j))$] $(p_i))$
$[[\text{It}]_{NPiSubj}$ $[\text{seems}]_{VPi}$ [[that] $[\text{Sheila}]_{NPjSubj}$
[has arrived]$_{VPj}$ $]_{CLi}$ $]_{Si}$

(26b) $(C_I$: [$(R_J)_{TOP}$ (T_I) $(T_J)_{FOC}$] $(C_I))$
$(p_i$: [(x_j) (f_i) (f_j)] $(p_i))$
[$[\text{Sheila}]_{NPiSubj}$ $[\text{seems}]_{VPi}$ [to [have arrived]$_{VPj}$ $]_{CLi}$ $]_{Si}$

In this way, syntactic configurations can be seen as the outcome of an interplay between interpersonal and representational considerations.

The Phonological Level

The phonological level accepts input from the Interpersonal and Morphosyntactic levels and provides input for the extragrammatical processes of articulation. In a complete FDG, the phonological level will be supplemented by a graphological and a gestural level, for written and signed communication, respectively.

FDG concentrates on those aspects of phonology that reflect the functioning of language in communication. Aspects directly influenced by the interpersonal level include the phonological reflection of the division of Moves into Acts. FDG distinguishes, in terms that anticipate the actional, temporally sequenced nature of phonetic activity, phonological Moves and phonological Acts, which in general correspond one to one with their congeners at the interpersonal level.

Within the phonological Act, the choice of Illocution type in many languages impacts upon the intonation: in languages such as Spanish, DECL and INTER Illocutions are rendered as distinct intonation contours, whereas in others (e.g., Japanese), this distinction is handled morphosyntactically, with little or no effect on the phonology. Similarly, the selection of the operator EXCLamative may bring about the selection of a marked word order template (for example), but is frequently encoded at the phonological level by relatively wide-ranging pitch movement; similarly, languages may make systematic use of phonological means to indicate an ironic intention.

Within the Act, such interpersonal functions as Topic and Focus, especially in languages where these have no morphosyntactic repercussions, must be indicated by relative accentual prominence. Distinctions between New, Contrastive, and Emphatic Focus may all be handled phonologically, as in English, cf. (1), where capitalization indicates the strongest accent:

(27a) She bought this beautiful DRESS. (New Focus)
(27b) She bought this BEAUTIFUL dress.
(Emphatic Focus)
(27c) SHE bought this beautiful dress.
(Contrastive Focus)

In other languages, these Focus contrasts may be reflected in morphosyntactic constructions or even lexically (i.e., via a Modifier).

The linear sequence emerging from the morphosyntactic template may be differently partitioned at the phonological level. Thus the template for Dutch subordinate clauses will place the complementizer *dat* in clause-initial P1 position and a 3rd person masculine pronominal subject in the following S position, as independent constituents; the phonological level will merge them into one phonological word:

(28)	MsL:	Ik	wou	dat	hij	kwam
		1ps	*want*.PAST	COMP	*3ps*	*come*.PAST
				P1	S	Vfin
		'I wish he would come.'				
	PhL:	/[kʋau]		[dɑti]		[kʋɑm]/

It is at the phonological level that segmental information about bound inflectional morphemes becomes available on the basis of paradigmatic knowledge. In Latin, for instance, the abstract suffix [–ACC.SING] will be placed at the morphosyntactic level but only at the phonological level will receive its form, e.g., */-am/* in the context of */femin-/* 'woman' and */-um/* in the context of */uir-/* 'man.'

Conclusion

Functional Discourse Grammar is a functional-typological theory of language that strives for psychological and pragmatic adequacy. This is reflected in its top-down organization, and in the fact that it takes discourse acts rather than sentences as the basic units of analysis. Within the underlying structure of utterances, four levels of analysis are distinguished. The form of utterances is accounted for as the outcome of the interaction between these levels. FDG has been developed on the basis of typological work, but at the same time offers important tools not only for typologists interested in syntactic and morphological typology, but also for those interested in pragmatic and semantic typology.

Functional Linguistics: A Short Historical Survey

In the course of the 20th century, the term 'functional' has been applied, on several occasions, to different types of linguistic practice. First of all, by members of the Prague Linguistic Circle, from the late 1920s onward, with a value close to the one that will be retained here. Later on, by Louis Hjelmslev with a sense reminiscent of its mathematical use and akin to that found in 'grammatical functions,' i.e., pointing to relations between items. More recently, it has been used by some followers of the transformational and generative trends, or by people initially influenced by, but departing from, them. As this article shows, the functional linguistics recommended employ 'functional' in its most usual meaning of 'adapted to achieve some end.' This use has been adopted, to some extent at least, by the members of the International Society for Functional Linguistics (= SILF, standing for the French Société internationale de linguistique fonctionnelle).

The first linguists who pointed to the necessity of a conscious functional approach were the Prague phonologists. In the wake of Karl Bühler (1931), they operated with the principle of abstractive relevance, according to which any scientific approach chooses a viewpoint that determines what observable facts shall be retained and what shall be disregarded as irrelevant for a given research. Experience has shown that the functioning and evolution of languages depends first and foremost on their use as communicative mediums. Therefore, communicative relevance is the first, if not the sole, relevance to be reckoned with.

In the same way as glossematics took shape as a reaction to Prague teachings, functional linguistics, stemming from the same Saussurian stock, has in many respects developed in contrast to glossematic positions (Martinet, 1977). The main features that characterize glossematics are (a) the constant parallelism between the two faces of the sign presented as expression and content, (b) the rejection of phonic and semantic substances in favor of pure relations, this leading to (c) the disregard of changes affecting substance, resulting in a tendency to equate the successive stages of a language and thereby leading to a purely static approach.

On these three points, functionalism is in total disagreement: (a) the asymmetrical pattern of double articulation into phonemes and monemes contrasts with Hjelmslev's isomorphic approach; (b) relevant substance is retained in order to qualify relations; and (c) changes in substance are found to pave the way toward a reshuffling of the relational network.

Operating with relevant substance leads to positing a functional linguistic reality. Linguistic structures are thus deemed to be facts with a real existence in human behavior and by no means, as widely assumed, mere contrivances of the descriptivists.

Contrasting with the enrichment derived from the permanent, even if antithetic, contacts between glossematicians and functionalists, the reaction of the latter to generativism has always been totally negative (Martinet, 1975: 82–88). The assumption of an innate language organization distinct from the various mental equipments of man was rejected from the start as gratuitous. The arbitrary and conflicting statements regarding a so-called deep structure were denounced as entirely subjective (Martinet, 1975: 231–32). The transformative operation was described as an unnecessary departure from an observation and comparison of real utterances leading to the establishment of syncretisms.

Functionalism was introduced into the UK by Jan Mulder, and later developed at St. Andrews University by Mulder and Sándor Hervey (1980). Its basically axiomatic basis has been emphasized and a logical apparatus devised that anticipates a confrontation with a large variety of linguistic facts, a procedure that contrasts with the more pragmatic, step-by-step 'continental' approach.

An Empirico-Deductive Approach

The obvious fact that languages differ through space and time is indicative of the nature of human language. It points to its constant adaptation to the varying needs of human communities. Contacts will breed linguistic convergence, with concomitant divergence among those who do not participate in the same contacts. This amounts to saying that communicating with language may be conducive to linguistic changes and, in short, that languages change because they function. Those who describe languages should take this into consideration and, by comparing the usages of coexisting generations, try to determine the direction and rhythm of their evolution.

The observation of natural languages has shown that they have a number of features in common – first of all, their communicative function. No one would

deny their fundamental contribution to the ordering of human experience. But this results from the analysis of that experience made necessary by the need to communicate it from person to person.

The next common feature is their use of vocal utterances. This is often forgotten – nay, intentionally omitted – by those who want to operate with relations rather than substance or do not feel at ease in phonic matters. The argument that some languages practically exist only in a written form is invalidated by the fact that they originated as spoken mediums and are organized accordingly. The linearity of speech could, in Saussurian terms, be considered irrelevant for 'language' proper, the occasional use of respective position in the spoken chain for indicating relations being bypassed as belonging to substance and not to the relational pattern. But it should be clear that if mankind had resorted to visual signs for interhuman communication, the analysis of experience, prior to its transmission, would have been of a totally different nature. Functionalists (Martinet, 1975: 26–29) do away with linearity in their two-dimensional visualizations. But they do not mean thereby that the auditory nature of linguistic exchanges that imposes that linearity has no bearing upon the way man perceives the world.

A third common feature is the double articulation of utterances into significant units whose perceptible form is, in its turn, articulated into distinctive units. Many linguists, even among functionalists, are tempted to argue that one could distinguish between more than two articulations, such as that of significant units into semantic features and that of distinctive units into distinctive features, which no one denies. But what is essential is the distinction between what is significant and what is just distinctive. Here again, those who refuse to consider the written form of a language as an additional code could argue that ideographic writing systems do not go beyond a first articulation. But they would thereby forget that all ideographic systems must at some point have recourse to phonic, i.e., distinctive nonsignificant, features.

By stipulation, we shall call 'a language' any form of human behavior that shares the above-mentioned three features. Arguing that the validity of our assertion has not been checked for all the past, present, and future 'languages' of the world does not make sense, because by means of our stipulation, we actually redefine the term 'language' and decide that it shall not be used in reference to any object that would not conform to our definition. All scientific terms should, of course, be carefully redefined.

Some linguists take exception to our stipulation by arguing that it leaves out some features that are obviously present in what all would agree to call a language, as, for instance, 'intonation,' or more generally prosodic or suprasegmental traits. The answer is that 'vocal,' in reference to linguistic utterances, implies 'voice,' which in its turn implies 'melodic curve,' which takes care of 'intonation.' Intensity and duration are similarly implied. For what purposes individual languages make use of the ingredients is not of concern here.

Our stipulatory, or should we say 'axiomatic,' approach takes care of what it has been fashionable to refer to as 'universals.' It would defeat our purposes to posit universals that are not implied in our formulation. Whatever does not conflict with it cannot be excluded from a language, be it positive or negative. For instance, the assumption that the distinction between noun and verb is universal cannot be made, because it is not implied by our definition. It should go without saying that being rendered in English by means of a verb or a noun does not make a foreign significant unit a verb or a noun. In other words, what is relevant in language A does not make it relevant in language B.

Functional Grammar

Functional grammar is concerned with the identification, classification, and functioning of significant units. It presupposes a phonology whose main task is the identification of distinctive units. It precedes a study of the lexicon, i.e., an examination of each significant unit, not taken care of in the grammar, in its relations to the analysis of man's experience.

The minimal linguistic unit combining an acoustically perceptible form and a reference to some aspect of experience is called a 'moneme.' Utterances are analyzed into monemes by means of the commutation test, which consists in looking for and comparing utterances that differ only on account of one minimal meaningful segment. A meaningful element is said to be minimal if it cannot be further analyzed into such segments. Many linguists refer to minimal significant units as 'morphemes.' But it is preferable to avoid this term, which suggests form rather than meaning. Once form has played its identifying role, only meaning should count, as implied by the term 'significant.' The linguistic ideal would seem to require that each meaning should always correspond to one and the same form and that one and the same form should always correspond to the same meaning. Actually, it frequently happens that the same meaning assumes different forms in different contexts as, e.g., *-s* in *cows* and *-en* in *oxen* with the same meaning 'plural,' and the same form assumes different meanings, as in *last* $\neq$ *first* and *last* = *to endure*. Here, *-s* and *-en* stand for the same moneme, $last^1$ and $last^2$ for different ones.

Among monemes identified by means of the commutation test, a first distinction is to be made between joint and free monemes: *farm* is free in *the farm was sold*, but joint in *farmer, farmyard*, and *farmhand*. A free moneme refers to a definite element of experience; a joint moneme, as such, does not. A combination of joint monemes is called a 'syntheme.' Free monemes and synthemes may receive determinations: *a big farm, a large farmyard, a strong farmhand*; joint monemes cannot. Synthemes commute with free monemes and maintain the same relations within the utterance. Therefore, what is said henceforth about monemes applies to free monemes and to synthemes as well. Complex monemes, such as participles, that share the compatibilities of different classes or present their own set of compatibilities are said to be 'parasynthemes.' Since individual speakers are free to make new synthemes according to certain patterns, 'synthematics,' which partially coincides with traditional 'word building,' belongs to grammar as an aspect of the functioning of significant units.

Speakers are not free to combine monemes at will if they want to be understood. The appearance of some type is often dependent on the presence of some other type. In such a case, the monemes of the former type are said to be 'subordinated' to those of the latter. Where no such restrictions exist, the monemes that are found to maintain the same relations to the context are said to be 'coordinated.'

Utterances consisting of several monemes are normally found to center around one of them or around two or more coordinated ones, which can be designated as the nucleus, the rest being its satellites. In *I worked on my father's farm*, the nucleus is *work-*; *I* enjoys a special status because its elimination would destroy the utterance. It is traditionally interpreted as what is talked about and accordingly called the 'subject.' Both *-ed*, as the form of the preterite moneme, and what follows are dispensable satellites. In *my father's farm, farm* acts as the nucleus of its satellite *my father's*. A specific designation was needed for the nucleus of the complete utterance. The term 'predicate' was chosen for that purpose, although it originally covered not only the nucleus but all its satellites except the subject.

What is called a 'verb' is a moneme that is used only as a predicate (or a predicatoid, i.e., the nucleus of a subordinate clause or, in other words, a full statement functioning as the satellite of another). Predicates are not necessarily verbs: in Russian *dom nov* 'the house is new', the predicate is *nov* 'new', but *nov* can function as a satellite in *nov-yj dom* 'new house'.

Some monemes never act as nuclei but always as satellites. They are called 'modalities' or 'modifiers.' They often appear as grammatical endings, such as the *-ed* of *worked*. But *my*, in *my father's*, is also a modality. A modality requires, of course, the presence of a nucleus.

A 'relator' (or 'functional') is a moneme that connects two monemes or moneme clusters, either coordinated or subordinated. Traditionally, coordinators such as *and, or, but* are called conjunctions; subordinators are conjunctions when they connect two clauses. They are prepositions, postpositions, or case endings elsewhere. A relator obviously requires the presence of two or more than two monemes or moneme clusters.

Another way of expressing the relation between nuclei and satellites is the use of 'determine' or its derivatives: the nucleus is said to be determined by its satellites, and the satellites are the determinants of the nucleus.

Monemes are said to be compatible with one another if they can meaningfully combine in an utterance. This does not necessarily imply contiguity: *farm* is found to be compatible with the article *the* in *the rich and big farm*.

Moneme classes are established on the basis of their mutual compatibilities. They are found to differ from one language to another. This was not generally assumed for the traditional parts of speech. Describers should not be led astray by the translations into their own language of the utterances they are analyzing. What appears as an adjective in a translation may well be a verb or a noun in the original. If, as has just been done here, the terms 'adjective,' 'verb,' and 'noun' are retained in reference to the moneme classes of a new language, they should be carefully redefined after a complete survey of the compatibilities of each class. It should not be assumed that all languages distinguish between adjective, verb, and noun classes.

Monemes belonging to a class are apt to be transferred to other classes: by dropping the moneme that a relator connects with the rest of the utterance, the relator ceases to be one and becomes the determinant of what precedes, as in *go through, stand for; blind* remains an adjective when it designates those who cannot see, but it is transferred to the noun class in *the blinds of the windows*. Cardinals, in French, which are constantly transferred from one class to another, may as well be considered as forming a class of their own.

Beginners should be warned against assuming the existence of a moneme when a formal distinction does not contribute any new information. This is the case of gender in a language like French. Except in some derivatives, the feminine gender in that language is manifested not in the noun itself but in its

determinants, articles, or adjectives. The word *classe* 'class' happens to 'be' feminine. All French speakers know that accordingly it requires feminine concord, which means that the use of the article *la* instead of *le* contributes no information whatsoever. Therefore, the feminine gender is not a moneme. In the same language, there is a female sex moneme that appears as *-esse* in *poétesse* 'female poet' or as *-ière* in *épicière* 'female grocer', as opposed to *épicier*, her male equivalent. But since the gender mark in the adjective *entière* 'entire' versus *entier* is homonymous, traditional grammarians are apt to confuse feminine gender, a morphological accident, and female sex, a full moneme.

In the same vein, no moneme should be posited for a gap in a grammatical paradigm. With a language with a past tense moneme and a future tense moneme, one is tempted to assume the existence of a present tense moneme. But in such languages, it is frequent that what is called the 'present' is formally identical with the bare stem of the verb, i.e., the verbal moneme itself. Should that form be restricted to the expression of events taking place precisely when the speech is being delivered, one would have to posit a present moneme with the positive meaning 'present' even if its form is zero. But as a rule, the bare stem is also found in reference to past and future events (cf. *call me before you come*) and generally when no definite time period is implied. In French, for instance, where personal endings are added to the bare stem in the so-called present tense, no present tense moneme should be identified. In English, where the present tense is positively characterized by third person singular *-s*, the existence of a present tense moneme could be argued.

The same remark applies to the singular number in languages where the bare stem is used for the species as well as for a unit, e.g., *man, the lion*. The same could be said about the indicative mood, which, again, normally coincides with the bare stem and just points to the existence of an event. But a zero form does not necessarily coincide with the absence of information: in Russian, the endingless *ryb*, among full forms such as *ryba*, *ryby*, harbors three distinct monemes with the meanings of 'fish,' 'plural,' and 'genitive.' Here again, what counts, when dealing with significant units, is meaning.

Generally speaking, concord amounts to repeating the same information in different places in the utterance, as, e.g., in Latin *bonorum vinorum* 'of good wines' where 'plural' and 'genitive' appear twice but are meant once. In the case of French gender, the *-a* of the article *la* is properly a part of the 'feminine' moneme *classe*. It is precisely what distinguishes *la voile* 'the sail' from *le voile* 'the veil.' In such cases, one operates with the discontinuous form of a moneme or, for short, a discontinuous moneme.

It is quite frequent that the commutation test confirms the presence of a moneme, but in such conditions one is not in a position to ascribe to it a definite segment of the utterance. This applies to Latin *vinorum*, where it cannot be discerned which parts of the total should be ascribed to 'wine,' 'genitive' or 'plural' respectively. In such cases, the forms of the monemes are said to be 'amalgamated.'

These various accidents should not prevent us from operating with monemes and incite us to resort to the traditional notion of 'word.' Even if it may prove useful in the description of a language like Latin, it cannot be accurately defined in general linguistics except in reference to the written forms of languages that make use of an alphabet. The closest one can get to pinning down the 'word' in the basic spoken form of language is by starting from the grammatical phrase, or syntagm. This consists in a nucleus with its various determinants and, as the case may be, a relator connecting it to the rest of the utterance. The largest grammatical phrase is the sentence, where whatever sounds as a relator (e.g., *but*) is actually transferred to some adverbial class, i.e., used as a determinant of the predicate. As an illustration of a full grammatical phrase, with all its ingredients, one can choose *of the large gardens* where *garden-* is the nucleus, *large* is a determinable determinant (as in *very large*), *the* and *-s* are modifiers, and *of* is the relator. The term 'syllemma' has been proposed for a grammatical phrase limited to its nucleus, its modifiers, and its relator. If the determinable determinant *large* is removed, the grammatical phrase is reduced to the syllemma *of the gardens*. Now, if in a syllemma the modifiers and the relator come before the nucleus, they are likely to be words in their own rights, as is the case here with *the* and *of*. If they come after, they will probably constitute a single word with the nucleus, as in *garden-s*. In *havernes*, the Danish equivalent of our syllemma, both the modifiers, *-er-* 'plural' and *-ne-* definite article, and the relator *-s* follow the nucleus, and the syllemma corresponds to what is called a 'word.' The reason for this difference of treatment is clear: significant segments are normally identified in speech before their final phonemes are uttered. It is therefore essential to preserve the identity of the initial part of each of them by avoiding amalgamation with what precedes, whereas that of the final part is less important and offers less resistance to blurring. One could be tempted to define the word as a syllemma where determinants and relator follow the nucleus. But there are exceptions, like Greek *elabon*

'I took', written as a single word in spite of the initial position of the modifier *e-*, a past tense moneme. Besides, such 'words' as *of* or *the*, being modifiers, cannot be identified as the nuclei of syllemmas. It should be clear that a functional grammarian is under no obligation ever to operate with the notion of syllemma.

Syntax is often conceived as dealing with the combinations of significant units (usually conceived as 'words') in utterances. Functionally, it is best understood as the study of how the hearer can manage to derive a meaning from a succession of significant units or, in other terms, to reconstruct, beyond the articuli of speech, the experience the speaker wants to communicate. It is, from the start, clear that relators like *-s* in *man's speech* or *of* in *the speech of man* should play a great role in such matters. But plain contiguity is often resorted to. The identification of a moneme as belonging to a certain class may suffice to indicate the nature of its relations to its neighbors: *good*, as an adjective, is known to qualify a following noun; *-ed* is known as a modifier of the verb to which it is tagged, and so forth. In other words, the first chapter of syntax will consist in the inventory of moneme classes, including, of course, all the compatibilities of each class.

This will suffice in a number of cases. But stating that in English verbs and nouns are compatible, the former as a nucleus, the latter as a satellite, does not give all the required information, because the mutual relations between verb and noun vary from one utterance to another and within the same utterance: the noun may act as a subject, an object, a beneficiary, an indication of time, space, or manner, and so on. These different functions may be indicated by means of the respective positions of verb and noun, e.g., the noun in subject function appearing before and that in object function after the verb. But this will have to be eked out by means of some relators, also referred to as 'functional indicators.' Another possibility is to coordinate several verbs, each one requiring its own determinants, as when *I write a letter to my son* becomes *I letter write give my son*. But of course *give*, in such a case, may be interpreted as resulting from a transfer from the verb class to that of subordinating relators.

Within a class, the nature of possible relations varies from one moneme to another. This is illustrated by the traditional distinction established between transitive and intransitive verbs. But in order to be exhaustive, one shall have to tell which verbs can combine with a beneficiary (e.g., *to give*), which verbs do not need a real subject (e.g., *to snow*) because the action referred to is conceived as self-sufficient, which verbs cannot appear without an object (e.g., *to put*), and so forth. In short, each moneme likely to act as a nucleus can be expected to maintain different relations with its satellites. The listing of all of these is best left to the lexicon, the grammarian, as such, being satisfied with the identification of the different types of relations for each moneme class.

As pointed out earlier in this article, the form of a moneme may vary from one context to another: *keep* appears as *kep-* before the preterite moneme /-t/, *have* is reduced to *ha-* before the /-d/ variant of the same modifier; *go* + the preterite appears amalgamated as *went*; the genitive moneme of Latin presents 10 different avatars. Concord is widely responsible for the formal variations of monemes. As suggested earlier, the material changes determined by concord should be ascribed to the moneme whose choice caused them. This rule, if strictly applied, would not only ascribe the *-a* of the definite article to the feminine noun that it accompanies but also every additional element that the choice of such a noun entails in the determining adjectives: if the French moneme for 'chair' is supposed to assume the form /-aʃɛz/ in *la chaise*, it will become /-a . . . -dʃɛz/ in *la grande chaise*, since no to /d/ is sounded in the masculine *grand*. Of course, once such variations have been identified as zero for the communication of information, one may be allowed to list the ones implied by the feminine gender of nouns in *see* **Adjectives**. In a similar way, using declensional patterns is probably the most sensible approach to the presentation of the forms of Latin cases. But one should not forget that the *-ibus* of *civibus* and the *-is* of *dominis* are linguistically identical, viz. datives and ablatives.

All of this belongs in the section on morphology in this encyclopedia. The unfortunately widespread opinion that morphology involves, and even consists in, the study of the relations between the components of the 'word,' just like syntax takes care of the relations between 'words,' should by all means be denounced as a misinterpretation of the contents of classical grammars.

Morphology, or accidence, is nothing but the presentation of the formal accidents that may complicate the task of youthful or adult learners, but do not have the least bearing upon the information utterances are meant to convey. Formal accidents may, of course, be prosodic as well as phonematic and also include deviations in the respective positions of monemes.

The insistence on a strict distinction between morphology and syntax as respectively negative and positive from the point of view of the success of communication and ease in the handling of the linguistic tool does not entail that each should be dealt with in two different articles. The presentation of each class should include a thorough survey of the

various accidents every one of the monemes involved may incur. But this should by no means exclude the possibility of dealing with some morphological facts prior to the listing of the classes. Such features as German umlaut, which affects the morphology of several moneme classes, are best presented in an introductory part of the grammar and referred to later when dealing with specific problems, such as plural of nouns, personal inflection of verbs, and so on. This means that the way morphology will be introduced in the grammar will depend on the nature of the formal accidents in the language at issue.

Grammar dealing with significant units, it is to be expected that semantics will not be absent from it. The problem is how much of it will be handled here and how much will be left for the lexicon. Spelling plays a role in this connection, because written 'words' will be included in the lexicon, but endings will be left out. This conflicts with the functional approach, which implies that modifiers and relators be handled together irrespective of whether they appear as 'words' or as parts of 'words.' Linguistic reality, as distinct from its formal vagaries, demands that, e.g., relators should be handled together and confronted, whatever form they may assume: endings, prepositions, or respective position. With this reservation, there is no reason to depart from the habit of dealing, in the grammar, with the semantic values of the units belonging to classes where they can be exhaustively listed and leaving those of others to the dictionary. In the same way that linguists distinguish in phonic matters between phonetics dealing with objective reality irrespective of its function, and phonology where matters are handled in reference to communicative relevance, it is recommended that a distinction be made between semantics proper, where differences of meaning are considered irrespective of whether they correspond to some formal difference, and axiology, where only relevant significant features are retained, namely those that are orally perceptible.

The describers of a language cannot hope to give an exhaustive presentation of all its varieties. Whether they should concentrate on an idiolect or a sociolect or try to cover a number of different usages depends on what their aims are. They might choose to concentrate on the spoken practice or cover the written form as well, and the problem arises of whether the two aspects should be dealt with separately, particularly in the case of an ideographic writing system. But even with an alphabetically written language, it may be advisable to present two different analyses, at least for some of the moneme classes. In standard written French, personal endings may differ from one verb to another. For present indicative first, second, and third singular, there is for *dorer* 'to gild', *-e*, *-es*, *-e*, in *je dores, tu dores, il dore*, but for *dormir* 'to sleep', *-s*, *-s*, *-t* in *je dors, tu dors, il dort*. In daily oral practice, all these endings are silent and all the forms sound /dɔr/ (note, with linking, the same pronunciation /dɔrtil/ for *dore-t-il?* 'does he gild?' and *dort-il?* 'does he sleep?'). This means that one has to operate in one case and with two different conjugations and first, second, and third singular, in another with verbs with the same radical throughout versus verbs with varying radicals: cf., e.g., *nous dorons* 'we gild' /dɔr-/ versus *nous dormons* 'we sleep' /dɔrm-/. Here is a situation where the distinction between spoken and written coincides with two different levels, one more solemn and one more spontaneous. But these are not necessarily confused: to familiar and slangy forms normally correspond written renderings, and rhetoric and ritual usages often present some specific oral features. All of this goes beyond grammar, involving as it does phonetics, phonology, and vocabulary, but it includes it.

hearer have something in common. Or, similarly, that a killer, a sender, and a dancer have something in common. Though it is true that a killer and a sender are not the same thing, they both instigate an event or action, usually volitionally. Therefore, they are purposefully instigating some event. Similarly, with the hearer and the believer, both are having some sort of internal experience, one perceptual and one cognitive. No event or action is being instigated in either case, nor is the experience normally volitional. Thus, they do have something in common. The generality problem can be formulated as follows. Given relations that are similar (for example, hearer, see-er, smeller, and taster can be classed together as perceivers; and believer, thinker, and knower can be classed together as cognizers), is it appropriate to postulate 'perceiver' and 'cognizer' as distinct thematic relations? Or is it appropriate to establish a more general role of 'experiencer' and then set up 'cognizer' and 'perceiver' as allorelations of that one more general relation?

These questions cannot be answered purely semantically, because both possibilities can be justified in semantic terms. The answer must, therefore, come from grammatical facts. This should not be surprising, since thematic relations are part of a general theory of grammar. It is necessary, then, to look and see if languages systematically treat perceivers and cognizers as different grammatically, or if they tend to treat them alike. It is generally the case that they do tend to be lumped together, receiving the same morphosyntactic treatment. But, on the other hand, many languages systematically treat experiencers differently from killers, senders, and dancers. In other words, an experiencer, which undergoes an internal state, is treated very differently in the grammar from purposeful instigators. In many languages, for example, subjects that are experiencers appear in the dative case, whereas those that are willful instigators appear in the nominative or ergative case. An example of this can be found in many Indo–European languages, e.g., Russian, Standard German (German), and Italian, in which some verbs of internal state use the so-called 'inverse construction': the experiencer is in the dative and the thing being experienced is in the nominative, e.g., German *das gefällt mir* (that[NOM] pleases me[DAT]) 'I like that.' This is opposed to *kill*, *send*, and *dance*, where the entities killing, sending, and dancing are in the nominative. Underlying the common treatment of experiencers is a neutralization of otherwise valid semantic contrasts within the grammar. It would be hard to argue, on any kind of reasonable 'grammatical' grounds, that believers ought to be separated from knowers, thinkers, expecters, and assumers. Since it would be hard to justify this, they are all grouped together as cognizers. Similarly, it would be hard to justify see-ers, feelers, hearers, touchers, smellers, and tasters as all being different; hence, they are all grouped together as perceivers. Clause-internal phenomena like case marking tend to treat them alike, and on these grounds they are often classed together under the general label of experiencer.

The fundamental issue here is to justify these distinctions on grammatical grounds, because ultimately, thematic relations act as an interface between lexical semantics and syntax. In other words, they do double duty. On the one hand, they are semantic in nature and related to the lexical semantic representation of the verb, because they are a function of the meaning of the verb. And the richer and more detailed the representation of the meaning of the verb, the more distinctions can be made. For example, a richer representation would permit the representation of the nuances that separate a believer from a knower. This is ultimately a part of a speaker's linguistic competence. But this distinction does not appear to be necessary for the grammar. On the one hand, these roles are a part of the lexical semantic representations of verbs, and on the other hand, they have grammatical implications. The thematic relations posited must be faithful to their semantic basis, but they also must be sensitive to the demands of grammar.

The solution to the problem of the correct inventory of thematic relations is ultimately a theory-internal issue; different theories and approaches have proposed inventories ranging from three to several dozen thematic relations. Since, as argued above, thematic relations must be justified grammatically as well as semantically, the grammatical justifications would be couched in terms of particular grammatical theories. Moreover, the size of the inventory depends crucially on the task(s) that thematic relations are assigned. There are two basic functions they can serve: (a) they can be part of the system of lexical representation, wherein they represent aspects of the verb's meaning (as in, e.g., Fillmore, 1968); and (b) they can play a role in the statement of grammatical rules, principles, or constraints. It is the first function that has led to large inventories of thematic relations: if they are used to capture meaning contrasts among verbs, then a large number will be needed to express the great variety of verbal semantic contrasts. If, on the other hand, their function is limited to the second one, then only as many will be needed as the syntax requires, and this is a much smaller number than that required for a lexical representation function.

Table 1

Agent: A willful, purposeful instigator of an action or event, such as in *John broke the glass*.

Experiencer: Things that experience internal states, such as perceivers and emoters (subjects of verbs like *think*, *believe*, *love*, and *hate*), as in *John thought about the question*.

Instrument: Usually inanimate things that are manipulated by an agent in the carrying out of an action, as in *John broke the window with the rock* or *The rock broke the window*. In both cases, *rock* is the instrument of an agent, whether the agent is specified or not.

Force: Involuntary causal participant that, unlike an instrument, cannot be manipulated. They can include things like *tornados, storms*, and *acts of God*, as in *The flood washed away the village*.

Patient: Things that are in a state or condition, or undergo a change of state or condition as in *John is tall, John is sick, The window broke*, and *John died*.

Theme: Things that are located or are undergoing a change of location (motion), as in *The book is on the table* or *John put the book on the table*.

Recipient: Someone who gets something (recipients are almost always animate), as in *He sent the book to John* or *He sent John the book*.

Goal: Destination, which is similar to recipient, except that it is inanimate, as in *He sent the book to Philadelphia*.

Source: The origin of an event or action. It is used in a variety of situations, which can conflate the ambiguity between recipient and goal:

	transfer	recipient
source x−y	⟶ z	
	motion	goal

(x = initial position, y = object, and z = final position)
If there is a transfer of *y*, then *z* is a recipient. If *y* is in motion, then *z* is a goal. In either case, *x* is the source, and *y* is the theme. No distinction is usually made between source of motion and source of transference, even though there is a distinction between recipient and goal.

Locative: A location. Path, source, and goal can be viewed as elaborations of different aspects of locatives. Locatives contrast with the others by referring to a situated location, such as in *The book is on the table*.

Path: A route, as in *He ran from the house, along the creek to the park*.

Though it would be quite impossible to review all of the inventories proposed by different theories, it is possible to construct a list of thematic relations that are standardly referred to in most accounts. This is given in Table 1.

One solution to the inventory problem suggested in Foley and Van Valin (1984) and elaborated in Van Valin (1993) is not to propose an absolute universal list of roles but rather to posit a universal semantic continuum in terms of which languages may make a varying number of distinctions. In this continuum of thematic relations, agent defines one end and patient the other; all of the other thematic relations

Figure 1

represent points along the continuum, and there is no absolute number of distinctions that every language must make, although there is strong evidence that certain of these distinctions are universal. The continuum may be represented as in Figure 1. The anchor points of the thematic relations continuum are agent (the willful, volitional, instigating participant) at one end and patient (the nonwillful, noninstigating, maximally affected participant) at the other. In between the polar entities, there is a continuum of semantic relations of more agent-like and patient-like roles. This continuum is flexible, for languages divide it up in different ways. There are, however, certain restrictions on the ways that it can be divided up.

Furthermore, the divisions are not random, for there are common divisions across languages. Languages distinguish entities that are affected in terms of their state or condition from those that are affected in terms of location. Therefore, they differentiate patients from things that are clearly at the right end of the scale but are less patient-like, namely themes. Themes are not affected in the same way and to the same degree, because they do not get crushed and chopped, but they do get moved around. Therefore, themes are clearly at the right end of the continuum and are not agent-like. On the other hand, there are things on the left side of this continuum that can be causal, but not instigating or controlling. Examples of this include instruments and forces. Further to the right, toward the center of the continuum, is the experiencer, which is the locus of an internal event, but is certainly not willful, volitional, and instigating. Many perceptual events are not volitionally instigated. The difference between verbs like *look at* and *see* is that the subject of *look at* is an experiencer that is also an agent, whereas the subject of *see* is simply an experiencer. In the middle of the continuum, there are all of the various types of locatives. In fact, many more can be found in the world's languages than are represented in Figure 1. Typically, things like recipient, source, goal, and path do not interact with one another, but rather with the theme. Figure 1 represents a continuum of distinctions, and languages may make more or fewer of them than what is listed above. This seems to be the semantic range that needs to be expressed in all languages. There appear to be as many

roles as can be motivated, as long as they fall on the continuum in Figure 1. And, in fact, the same distinctions recur across languages; the same contrasts between experiencer and agent, instrument and agent, theme and locative, and so on, are found in language after language.

Jackendoff (1987) took a somewhat different approach to specific thematic relations. He posited several tiers of thematic relations: an action tier and a temporal tier in addition to the basic level of the thematic tier. The thematic tier deals with motion and location, the action tier deals with attributions of responsibility and affectedness, and the temporal tier deals with aspectual properties of events. The thematic tier is primarily concerned with the roles of theme, goal, and source, whereas agent and patient appear only on the action tier. This is exemplified in (1), with examples from Jackendoff (1987).

(1) (a) The car [Theme_{TH}] hit the tree [Goal_{TH}; Patient_{AC}].
(b) Pete [Source_{TH}; Agent_{AC}] threw the ball [Theme_{TH}; Patient_{AC}].
(c) Bill [Theme_{TH}; Agent_{AC}] entered the room [Goal_{TH}].

('TH' denotes a role from the thematic tier; 'AC' denotes one from the action tier.)

In this scheme, an argument may bear multiple specific thematic relations, each reflecting one facet of its interpretation.

Generalized Thematic Relations

It has been proposed that a second, more general type of semantic relation must be posited: 'semantic macroroles' or 'semantic proto-roles.' Originally proposed in Van Valin (1977) and further developed in Foley and Van Valin (1984) and subsequent work, semantic macroroles are generalized semantic relations that subsume groups of specific thematic relations. There are two macroroles, 'actor' and 'undergoer.' They are the two primary arguments of a transitive predication, corresponding to the general senses of 'agent' and 'patient' discussed above, either one of which may be the single argument of an intransitive verb. They correspond to what is pretheoretically commonly called 'logical subject' and 'logical object.' Macroroles are motivated by the fact that in grammatical constructions groups of thematic relations are treated alike. This is illustrated in (2)–(4).

(2)	(a) *Fred* broke the window.	Agent
	(b) *The bomb* destroyed the car.	Instrument
	(c) *Mary* received a parking ticket.	Recipient
	(d) *The farm animals* sensed the earthquake.	Experiencer
	(e) *Stars* emit light.	Source
(3)	(a) Max tossed *the book* to the teacher.	Theme
	(b) The tidal wave destroyed *the harbor.*	Patient
	(c) The rock hit *the wall.*	Locative
	(d) The mugger robbed *Tom* of $45.00.	Source
	(e) Will presented *Sheila* with a bouquet.	Recipient

(4)	(a) The window was broken by *Fred*.	Agent
	(b) The car was destroyed by *the bomb*.	Instrument
	(c) The earthquake was sensed by *the farm animals*.	Experiencer
	(d) *The book* was tossed to the teacher by Max.	Theme
	(e) *The harbor* was destroyed by the tidal wave.	Patient
	(f) *The wall* was hit by the rock.	Locative

In (2), agent, instrument, recipient, experiencer, and source are all treated as the actor and subject of a transitive verb, whereas in (3), theme, patient, locative, source, and recipient are treated alike as the undergoer and object of a transitive verb. These groupings are not equivalent to (surface) grammatical relations like subject and direct object, for they hold in passive constructions as well, as illustrated in (4); here the undergoer is the subject and the actor the object of *by*. If this alternation were to be stated in terms of specific thematic relations, then long disjunctive lists of thematic relations would be required: in an active clause, the agent, instrument, recipient, experiencer, or source is the subject and the theme, patient, locative, source, or recipient is the object, whereas in a passive clause the theme, patient, locative, source, or recipient is the subject and the agent, instrument, recipient, experiencer or source is the object of *by*. This is an undesirable analysis, as it clearly does not capture what is going on. Alternatively, a formulation in terms of macroroles is much simpler: in an active clause, the actor is the subject and the undergoer is the direct object, whereas in a passive clause the undergoer is the subject and the actor is the object of *by*.

With intransitive verbs, similar generalizations hold. Some intransitive verbs take an actor as their single argument, and others take an undergoer. This is illustrated in (5)–(6).

(5)	(a) *David* sang loudly.	Agent
	(b) *The ball* flew over the fence.	Theme
	(c) *The motor* is running well.	Instrument
(6)	(a) *The dog* was sitting on the table.	Theme
	(b) *Larry* got fat.	Patient
	(c) *Marge* felt sick.	Experiencer

The subjects in (5) are all actors, despite the range of thematic variation, and those in (6) are undergoers.

Figure 2

As with transitive verbs, each macrorole subsumes a number of specific thematic relations.

Dowty (1991) proposed two generalized thematic relations, which he called 'proto-roles'; they are 'proto-agent' and 'proto-patient.' They are similar in certain respects to actor and undergoer, but they are embedded within a very different theoretical outlook: Dowty claimed that proto-roles are the only valid thematic relations, and he denied the validity of specific thematic relations like agent, theme, and patient. Proto-roles are constellations of features that define a prototype; they are not generalizations of specific thematic relations, unlike macroroles.

The relationship between specific and generalized thematic relations is captured in Figure 2, which represents the increasing generalization and neutralization of semantic distinctions involved in them. (Not all specific thematic relations and not all groupings of specific thematic relations into generalized relations are illustrated).

Role of Semantic Relations in Syntactic Theories

Most syntactic theories employ semantic relations in some way; Generalized Phrase Structure Grammar (GPSG) (Gazdar *et al.*, 1985) and Montague Grammar (MG) (e.g., Dowty, 1979) are the major exceptions (*see also* **Montague Semantics**). Specific thematic relations are a central feature of lexical entries for verbs in both Government-Binding Theory (GB) (Chomsky, 1981) and Lexical Functional Grammar (LFG) (Bresnan, 1982); they are assumed to be part of the lexical entries for verbs in work in Relational Grammar (RelG) (Perlmutter, 1982), but there is no explicit discussion of either thematic relations or lexical entries within RelG (*see also* **Word Order and Linearization**).

Thematic relations function differently in GB and LFG. The list of (specific) thematic relations associated with a verb, its *θ-grid*, plays a central role in the GB system; syntactic subcategorization information is deduced from it, and this in turn underlies the constraints imposed by the Projection Principle. D-structure is assumed to be a *pure* syntactic representation of the argument structure of a verb, which is represented by the θ-grid. Moreover, θ-role assignment is an important part of the derivation of a sentence, and the principle that governs it, the θ-criterion, is one of the major constraints in the GB

system. In LFG, on the other hand, θ-roles are associated with grammatical relations (called grammatical functions' in LFG) in the lexical entries of verbs, and lexical rules operate to change the linkings between thematic relations and grammatical functions, e.g., passive relinks the agent from subject to oblique and the theme from object to subject. In both theories, θ-roles serve as the primary means for representing the *meaning* of a verb, but neither theory assumes an explicit theory of lexical semantics or proposes any independently motivated principles that govern the assignment of specific θ-roles to particular verbs. This is more of a problem for LFG than GB; in GB nothing depends on which θ-role an argument receives, as long as it receives one (and only one), whereas in LFG the validity of the syntactic analysis depends crucially in many instances on the identity of the θ-role assigned, e.g., the analysis of locative inversion in Chichewa in Bresnan and Kanerva (1989). Hence, without independent criteria for determining which θ-role an argument is linked to, the validity of such analyses is open to serious question. Thus, though thematic relations are an important feature of the GB and LFG systems of lexical representation for verbs, their respective functions within the overall theory are very different in the two frameworks.

The only theory that makes use of both specific and generalized thematic relations is Role and Reference Grammar (RRG) (Foley and Van Valin, 1984; Van Valin, 1993; *see* **Role and Reference Grammar**). RRG posits only one level of syntactic representation, unlike GB and RelG, and θ-roles, especially macroroles (generalized thematic relations), serve a crucial function in the linking of semantic and syntactic representations. Some of the generalizations captured by macroroles (see (2)–(6) above) are handled in other theories by D-structure (GB)/initial stratum (RelG) grammatical relations, but macroroles are not equivalent to underlying grammatical relations (see Van Valin, 1990). Unlike GB and LFG, θ-roles are not part of the scheme for lexical representation of verbs; this is accomplished by a modified version of the system of lexical decomposition proposed in Dowty (1979). Moreover, there are independent principles governing the association of specific θ-roles with particular verbs, and therefore RRG is the only theory in which the assignment of thematic relations to verbs is independently motivated.

Pragmatic Functional Relations

Pragmatic functional relations are concerned with the distribution of information in utterances, in particular with respect to what is assumed by the speaker to be known to interlocutors and what is presented as new and informative. Research on this type of functional relation goes back at least to the Prague School linguists (*see* **Prague School**) of the 1920s, e.g., Mathesius (see **Mathesius, Vilém (1882–1945)**), and has continued in modern work, e.g., Firbas (1966). Pragmatic relations have played a role in contemporary linguistic theory and description in the work of Halliday (1967, 1985), Jackendoff (1972), and Kuno (1972a,b; 1975), among others.

There is a fundamental distinction in information structure that all of these different approaches seek to capture, namely that between the material in an utterance that is presented by the speaker as assumed to be known, accessible, or recoverable from context by interlocutors and that which is presented by the speaker as unknown, inaccessible, and not recoverable, hence as new and informative. Different approaches vary with respect to both how this contrast is labeled and exactly how the opposition is defined, but this basic distinction underlies all of them. In Prague School work, for example, 'theme' (known, given) is distinguished from 'rheme' (unknown, new), whereas in most contemporary work the terms 'topic,' 'focus,' and 'presupposition' are employed. They may be characterized as follows, following Lambrecht (1986, 1987, 1988).

> *Pragmatic presupposition*: 'The proposition or set of propositions which the speaker assumes the hearer considers true (believes, knows) and is aware of at the time of the utterance and which is relevant in the context of utterance.' (Lambrecht 1988: 1)

> *Topic*: 'What must be presupposed in the case of a topic is not the topic itself, nor its referent, but the status of the topic reference as a possible center of interest or matter of concern in the conversation. . .[T]he topic reference is *active* or *accessible* in the discourse. . .[T]he topic is contained in the pragmatic presupposition or is an element of the pragmatic presupposition.' (Lambrecht, 1986: 102)

> *Focus*: The focus of an utterance is the non-presupposed part of the utterance; it is the part that is asserted in a declarative utterance and questioned in an interrogative utterance. In English and many other languages, it is indicated by prosodic prominence.

These notions are derivable from Kempson's (1975) reformulation of Grice's (1975) maxim of quantity (see Van Valin, 1991). They are universal, as they follow from the essential communicative function of language.

Lambrecht proposed a typology of information structure patterns with different topic–focus arrangements. The least marked one distributionally involves a topical subject and a focal predicate and

corresponds to the traditional 'topic–comment' bifurcation of clauses; he labeled it a 'predicate focus construction.' Presentational sentences like *There arose a great storm* lack a topical lexical subject NP and contain virtually all focal material; these are termed 'sentence focus constructions' by Lambrecht and 'neutral description utterances' by Kuno (1972a,b). Finally, utterances in which the focus is restricted to a single constituent, e.g., the answer to a wh-question, are called 'narrow focus constructions.' These constructions are found in all languages, and a variety of means are employed to signal them. English distinguishes them primarily by means of prosody and clefting. Japanese uses particles: unstressed *wa* marks the topic(s) in a predicate focus construction, stressed *wa* and stressed *ga* ('exhaustive listing *ga*' in Kuno) mark narrow focus constructions, and unstressed *ga* indicates sentence focus constructions. Italian employs word order, prosody, and clefting: predicate focus involves (S)VO order, sentence focus VS order, and narrow focus a cleft in which the focus NP appears postverbally in the matrix clause (see Lambrecht, 1986, 1987, 1993, for detailed discussion).

It has long been noticed that there appear to be correlations between information structure and grammatical structure. Given that in the vast majority of languages topical, presupposed material tends strongly to precede focal, non-presupposed material in utterances, constructions that involve displacement of elements from their default position to the left toward the onset of the utterance could be analyzed as having a topicalizing function, whereas those that entail the displacement of elements to the right toward the end of the utterance could be analyzed as having a focalizing function. Subject inversion in Romance languages like Italian and Spanish, for example, can be viewed as motivated by the need to place the subject in the immediately postverbal focus position in these languages in a sentence focus or narrow focus construction. Similarly, passivization can be interpreted as a construction in which the undergoer, which would normally appear in the pre (OV)-/post(VO)-verbal focus position, occurs instead in the normally topical subject position, as a reflection of its topical status in the discourse context, while the actor, the topical subject in the default case, appears in the normally focal portion of the utterance (if it appears at all). The occurrence of normally clause-internal material in utterance-initial position, as in topicalization and left-dislocation constructions, is another example of pragmatically motivated syntax (see, e.g., Prince 1981a,b; Horn, 1986).

Most syntactic theories simply ignore pragmatic functions. To the extent that the correlations noted above between syntactic structures and pragmatic functions are acknowledged, it is nevertheless considered to fall outside of the realm of grammar. Only two of the theories mentioned above make any systematic use of these functions, namely, LFG and RRG. Both theories recognize all three types of functional relation, but they are treated differently in them. LFG views them as autonomous, and an argument can be described in terms of all three independently; that is, a subject can be an agent or a theme and a topic or a focus, for example. In RRG, on the other hand, syntactic (grammatical) relations are analyzed as being grammaticalizations of semantic and pragmatic relations, as is discussed in the next section. Hence, they are not an autonomous type of relation as in LFG.

Syntactic Functional Relations

Syntactic functional relations, or grammatical relations, are the focus of considerable controversy within syntactic theory. Some theories, e.g., RelG and LFG, consider them to be a fundamental and indispensable component of linguistic theory and analysis. Others, e.g., GB and RRG, treat them as derivative of other, putatively more basic concepts, and GPSG ignores them altogether. GB derives grammatical relations from phrase-structure configurations: subject is the NP immediately dominated by S (Chomsky, 1965), or, more recently, SPEC(ifier) of IP (=INFL″ =S) (Chomsky, 1986), and object is the NP immediately dominated by VP (Chomsky, 1965) or V′ (Chomsky, 1986). The RRG theory of grammatical relations differs markedly from all generative accounts, and it discussed below.

Grammatical Relations

Since both LFG and RelG claim to be theories of universal grammar, their postulation of grammatical relations as fundamental components of linguistic theory raises the vital issue of their universality. If valid cross-linguistic universals are to be stated in terms of them, then they must themselves be universally valid constructs. The first step in ascertaining their validity as primitive (nonderived) theoretical constructs is characterizing them in such a way that their existence in a grammatical system can be demonstrated.

A grammatical relation exists when there is a restricted neutralization of semantic roles for syntactic purposes. Grammatical relations result from the extension of the pattern of neutralization represented in Figure 2 to the neutralization of all semantic role contrasts. Consider the following examples from English (7):

(7) (a) Henry seems to be singing in the shower.
(b) Henry seems to be elated.
(c) Henry seems to be listening to a new CD.
(d) *Henry$_i$ seems Louise to have embarrassed_____$_i$.
(e) Henry seems to have been embarrassed by Louise.

In (7) an argument of the dependent clause appears in the matrix clause. In (7a), the 'raised' argument is the actor of the intransitive verb *sing*, and in (b) it is the undergoer of the intransitive predicate *be elated*. The verbs in the remaining examples are transitive; the raised argument in (c) is the actor of *listen to*, and in (d) and (e) it is the undergoer of *embarrass*. It is clear that the restriction on which argument can be raised cannot be stated in semantic role terms: it can be either an actor or an undergoer, and the crucial contrast between (d) and (e) cannot be explained in purely semantic terms. Rather, it must be accounted for syntactically: the argument that can be raised is the one that bears a particularly syntactic relation in the dependent clause, and it bears this relation in the passivized dependent clause in (e) but not in the active clause in (d) in which it has a different syntactic function. Hence, there is a restricted neutralization of semantic roles with regard to which argument of the dependent clause can appear in the matrix clause, and the relation that this neutralization defines is the traditional notion of 'subject' for English. The same argument can be made with respect to the relation that triggers finite verb agreement in (7); it cannot be characterized semantically, because all semantic role possibilities are represented in (7a, b, c, e). (Note that it makes no difference for this argument whether specific or generalized thematic relations are assumed.) Here again, a restricted neutralization defines the same syntactic relation as in the raising construction.

Grammatical relations are defined only by restricted neutralizations of semantic roles; neither unrestricted neutralizations nor restrictions without neutralization define a syntactic relation. An example of an unrestricted neutralization is relativization with a wh-relative pronoun in English. This clearly involves a neutralization of semantic roles, as the relativized NP can bear virtually any thematic relation, specific or general, to the predicate in the relative clause. This is illustrated in (8).

(8) Mary talked to the man
(a) who [actor, agent] bought the house down the street.
(b) who [undergoer, patient] the dog bit.
(c) to whom [recipient] Bill showed the house.
Mary looked at the box
(d) in which [locative] the jewelry was kept.
(e) out of which [source] the jewelry had been taken.

There appear to be no semantic restrictions of the relevant type on the relativization strategy in English, and therefore this is an example of a neutralization of semantic roles for syntactic purposes. However, this construction does not define a grammatical relation in English, unlike raising and finite verb agreement, because it is not restricted. The converse, a restriction without neutralization, can be found in possessor ascension in Aceh (Acehnese), an Austronesian language spoken in Sumatra. The basic facts are presented in (9), from Durie (1987).

(9) (a) Seunang até lôn.
happy liver 1SG
'I am happy.' (lit: 'My liver is happy.')
(b) Lôn seunang-até.
1SG happy-liver
'I am happy.'
(c) Ka lôn-tët rumoh gopnyan.
IN 1SGA-burn house 3SG
'I burned her house.'
(d) Gopnyan ka lôn-tët-rumoh.
3SG IN 1SGA-burn-house
'I burned her house,' or 'She had her house burned by me.'
(e) *Gopnyan ka aneuk-woe.
3SG IN child-return
'His/her child returned.'

Possessor ascension is possible only if the possessed argument functions as an undergoer in the clause; the transitivity of the verb is irrelevant. In (9a), the single argument of *seunang* 'be happy' is *até lôn* 'my liver,' which is the undergoer of the stative predicate. In (9b), *lôn* 'I' functions as subject and *até* is compounded with *seunang*. In (9c), the undergoer of the transitive verb *tët* 'burn' is *rumoh gopnyan* 'his/her house,' whereas in (9d), the possessor *gopnyan* 'he/she' appears as an independent argument and *rumoh* 'house' is incorporated into the predicate. This is impossible with the possessor of an actor argument, as (9e) shows. Thus possessor ascension in Acehnese involves a definite restriction, i.e., the possessed NP must be an undergoer argument, but there is no neutralization of semantic roles; consequently, the relation specified is not a syntactic (grammatical) relation but rather a semantic one. It is only when there is both a restriction and a neutralization that a grammatical relation is involved.

If one were to investigate every major syntactic construction in English, it would be seen that the results were either like that in (7), in which a particular

restricted neutralization is found, or like that in (8), in which there is a neutralization without a restriction. The pattern of restricted neutralizations across constructions is very consistent in English, and it is this pattern that constitutes and defines the grammatical relation 'subject' in English. Grammatical relations are consistent patterns of restricted neutralizations in a language.

Universal Grammatical Relations

There are two senses in which grammatical relations could be considered universal, a strong one and a weaker one. The strong sense is that there are grammatical relations in every human language. That is, in the grammar of every human language there is at least one construction in which there is a restricted neutralization of semantic roles for syntactic purposes. If it can be demonstrated that there is at least one language in which this is not the case, then grammatical relations are not universal in the strong sense. The weaker sense of universality is that in all of the languages that have grammatical relations, they play the same role in every language. This is based on the Saussurean notion of linguistic 'value': two linguistic entities are the same if they have the same value; i.e., they enter into the same relations of co-occurrence and contrast within the linguistic system (*see* **Saussurean Tradition in 20th-Century Linguistics; Saussure, Ferdinand (-Mongin) de (1857–1913)**). This weaker sense of universality is, then, the claim that grammatical relations in different languages have the same value in each linguistic system. In this domain, value is determined by the restricted neutralizations defining the relations: two systems of grammatical relations are the same if they are defined by the same (or comparable) restricted neutralizations.

As noted above, grammatical relations are not universal in the strong sense if there is a single language that exhibits no restricted neutralizations in its grammar. Acehnese is such a language, as argued in Durie (1987): there are restrictions without neutralizations, as in (9), and neutralizations without restrictions, as in (8), but there are no restricted neutralizations of semantic roles for syntactic purposes in the language. The full range of Acehnese data cannot be presented here, but three representative sets can be given. Grammatical constructions fall into three groups in this language: those in which only actor arguments may be involved, those in which only undergoer arguments may be involved, and those in which any argument of the verb may be involved. The second type has already been exemplified in (9). Before presenting the other two, it is necessary to give a brief introduction to verb classes and agreement in Acehnese. All examples are from Durie (1987).

Acehnese transitive may carry agreement clitics cross-referencing both primary arguments, the actor and the undergoer. This is illustrated in (10).

(10) (a) Gopnyan geu-mat lôn./geu-mat-lôn.
3SG 3A-hold 1SG/3A-hold-1SGU
'(S)He holds me.'
(b) (Lôn) lôn-mat gopnyan.
1SG 1SGA-hold 3SG
'I told him/her.'

The clitics for actor and undergoer have the same basic form; they are distinguished by position, with actor signaled by a proclitic and undergoer by an optional enclitic. Thus *geu-* cross-references the actor and *-lôn* the undergoer in (10a), whereas *lôn-* cross-references the actor in (10b). Intransitive verbs fall into two general classes in terms of which agreement they take: some take only actor proclitics, e.g., *jak* 'go,' and the others take only the undergoer enclitics, e.g., *rhët* 'fall.' This is exemplified in (11).

(11) (a) (Gopnyan) geu-jak. /*gopnyan jak(-geuh).
3SG 3A-go go(3-U)
'(S)He goes.'
(b) (Lôn) lôn-jak./*lôn jak(-lôn)
1SG 1SGA-go go(-1SGU)
'I go.'
(c) Gopnyan rhët(-geuh)./*gopnyan geu-rhët
3SG fall(-3U) 3_A-fall
'(S)He falls.'
(d) Lôn rhët(-lôn)/*lôn lôn-rhët
1SG fall(-1SGU) 1SGA-fall
'I fall.'

Constructions involving the verb *tém* 'what' can only have complements in which the verb takes an actor argument, and the cross-reference clitic for the actor is obligatorily omitted; intransitive verbs that take only an undergoer argument are impossible in this construction, and with a transitive verb the omitted argument must always be the actor, never the undergoer. This is illustrated in (12).

(12) (a) Gopnyan geu-tém [(*geu-)jak].
3SG 3_A-want go
'(S)he wants to go.'
(b) Geu-tém [(*geu-)taguen bu].
3-want cook rice
'She wants to cook rice.'
(c) *Gopnyan geu-tém [rhët].
3SG 3_A-want fall
'(S)he wants to fall.'

(d) *Aneuk agam nyan ji-tém
child male that 3_A-want
[geu-peuréksa lé dokto].
3_A-examine by doctor
'That child wants to be examined by the doctor.'

(The Acehnese construction in (12d) is not a passive; see Durie (1988) for detailed arguments. *Geu-* and *ji-* are both third person but differ in the social status they code; *geu-* cross-references the higher status doctor, whereas *ji-* agrees with the lower status child.) Both *jak* 'go' and *taguen* 'cook' take actor arguments, and the actor clitic is obligatorily omitted in the dependent clause in (12a, b). *Rhët* 'fall,' on the other hand, takes only an undergoer argument, and it is impossible in this construction, as (12c) shows. In (12d), the omitted argument in the complement clause must be interpreted as the undergoer, and the result is ungrammatical. Thus, this construction is restricted to verbs that take an actor argument, and the actor argument must be omitted; this is an example of a restriction without a neutralization. The difference between this construction and the one in (9) is that possessor ascension is restricted to undergoer arguments only, whereas this one is restricted to actor arguments only. These two constructions are representative of the majority of syntactic constructions in Acehnese.

There are, however, constructions that involve an unrestricted neutralization, e.g., raising. This is exemplified in (13).

(13) (a) Gopnyan teuntèe [geu-woe].
3SG certain 3A-return
'(S)he is certain to return.'

(b) Gopnyan teuntèe [meungang-geuh].
3SG certain win-3U
'(S)he is certain to win.'

(c) Gopnyan teuntèe [geu-beuet hikayat prang sabi].
3SG certain 3A-recite epic
'He is certain to recite the Prang Sabi epic.'

(d) Hikayat prang sabi teuntèe [geu-beuet].
epic certain 3A-recite
'The Prang Sabi epic is certain to be recited by him.'

(e) Gopnyan lôn-anggap [na neu-bi pèng baroe].
3SG 1SG-consider be 2A-give money yesterday
'I believe him to have been given money by you yesterday.'
(lit.: 'I consider him_i [you gave money [to]$______i$ yesterday].')

The raised argument is an actor in (13a, c), an undergoer in (b, d), and a recipient argument in (e); Durie stated that any core argument of the verb can be raised in this construction. Hence in this construction, unlike the others, there is a neutralization of semantic roles for syntactic purposes, but it is not restricted. Therefore, it does not define a grammatical relation. Neither actor nor undergoer nor 'any argument of the verb' constitutes a grammatical relation.

Acehnese thus presents an example of a language that exhibits no restricted neutralizations of semantic roles in its syntax and therefore lacks grammatical relations as defined above. Another example of such a language is Mandarin Chinese; Li and Thompson (1976) argued that pragmatic functional relations are the relevant relations in Mandarin grammar, and LaPolla (1990) showed that there is no evidence to support the positing of purely syntactic relations in Mandarin syntax. Consequently, the strong sense of universality cannot be maintained. The validity of the weaker sense can be tested by contrasting English with Warlpiri (Andrews, 1985), a language of Central Australia. The construction to be examined involves omission of an argument in a dependent clause; it is illustrated in (14).

(14) Ngaju-rlu Ø-rna yankirri pantu-rnu,
I-ERG AUX-I emu (ABS) spear-PAST
ngapa nga-rninyja-kurra
water (ABS) drink-INF-while
'I speared the emu while it (not I) was drinking water.'

Andrews stated that the missing argument in the *-kurra* construction is always the subject of the nonfinite clause. In semantic role terms, the omitted argument is the actor of *nga-* 'drink.' The actor argument of an intransitive verb can also be omitted, and in the sentences in (15) the omitted argument in each is the undergoer of an intransitive verb.

(15) (a) Ngaju ka-rna-ngku mari-jarri-mi
I(ABS) PRES-I-you grief-being-NONPAST
nyuntu-ku, murumuru nguna-nyja-kurra-(ku)
you-DAT sick lie-INF-while-(DAT)
'I feel sorry for you while you are lying sick.'

(b) karli Ø-rna nya-ngu
boomerang(ABS) AUX-I see-PAST
pirli-ngirli wanti-nyja-kurra
stone-ELATIVE fall-INF-while
'I saw the boomerang fall from the stone.'

In (15a), the verb is *nguna* 'lie' as part of the expression 'lie sick,' which can plausibly be assumed to be nonvolitional since people do not volitionally lie sick, and in (15b) it is *wanti* 'fall.' These two verbs do not take actors as their single argument, and yet it is possible for it to be omitted in this construction. This shows that the restriction on which argument is omitted in the dependent clause cannot be stated in purely semantic role terms. Therefore, with

Table 2 Restricted neutralization of semantic roles

	Intransitive Vs	*Transitive Vs*	*Grammatical relations*
Acehnese	No	No	No
English	Yes	Yes	Yes
Warlpiri	Yes	No	Yes

intransitives, there is an example of a restricted neutralization of semantic roles for syntactic purposes in Warlpiri, and this shows that the language has grammatical relations.

Is there an analogous neutralization in sentences with transitive verbs? The restricted neutralization in (14) and (15) parallels that in English in (7a, b) with intransitive verbs and (7c) with an active voice transitive verb. In English, there is a restricted neutralization with transitive verbs, as shown in (7c, d, e); the relevant Warlpiri example is given in (16).

(16) *Yankirri Ø-rna nya-ngu
emu(ABS) AUX-1SG see-PAST
ngarka-ngku pantu-nyja-kurra.
man-ERG spear-INF-while
'I saw the emu$_1$ while the man speared___$_1$'.

It is impossible for the omitted argument in the dependent clause to be interpreted as the undergoer, in sharp contrast to (7e) in English, and therefore the restricted neutralization in Warlpiri is limited to intransitive verbs. The facts in (14)–(16) are representative for the language as a whole. The situation in Acehnese, English, and Warlpiri is summarized in Table 2. Even though grammatical relations can be motivated in both English and Warlpiri, the restricted neutralizations defining them are not the same: in English, the neutralization applies to the arguments of both transitive and intransitive verbs, whereas in Warlpiri, it is only with intransitive verbs. Thus, subject in Warlpiri cannot be considered to be exactly the same as subject in English, and therefore the weaker sense of universality is also insupportable. It must be emphasized that the reason for this contrast is not due to the fact that Warlpiri has ergative morphology and English accusative; Dyirbal, another Australian language (Dixon, 1972), has both ergative morphology and syntax, and yet with respect to these criteria, it patterns like English, not Warlpiri, in that it exhibits restricted neutralizations with both intransitive and transitive verbs. Though this discussion has focused on just these three languages, many examples of English-type and Warlpiri-type languages could be adduced (see Foley and Van Valin, 1985; Van Valin, 1993). It appears, then, that grammatical relations are not universal in either sense.

Figure 3

Types of Systems of Grammatical Relations

Systems of syntactic relations vary along three primary dimensions: the pattern of the relations, the factors affecting the relations, and the consistency of the relations. Each of these is discussed below.

The pattern of grammatical relations refers to the contrast between languages with accusative syntax and those with ergative syntax. In characterizing ergativity, it is useful to distinguish what Andrews (1985) called 'grammatical functions' from grammatical relations. Dixon (1972) proposed that there are three grammatical functions: 'S,' the single argument of an intransitive verb; 'A,' the actor of a transitive verb; and 'O,' the object of a transitive verb. Grammatical relations are constituted of combinations of the functions. In English, the grammatical relation 'subject' includes both S and A, whereas the 'direct object' encompasses only O. This is clear from the facts in (7): S and A are treated alike, as in (7a, b, c), whereas O is excluded from the construction, as (7d) shows. In order for an undergoer of a transitive verb (which is normally realized as the O) to be raised in this construction, it must function as the derived intransitive subject of a passive verb; this grammatical function will be labeled 'd-S.' This pattern (subject = [S, A, d-S], object = [O]) defines an 'accusative' pattern. The name comes from the case marking pattern in languages like German in which S and A receive nominative (unmarked) case and O receives accusative (marked) case. In an ergative language, the grouping of functions is different, at least for some grammatical phenomena. With respect to case marking, S and O are assigned absolutive (unmarked) case, and A receives ergative (marked) case. There are also syntactic phenomena in some ergative languages, e.g., Dyirbal (Dixon, 1972), Sama (Walton, 1986), and (Jacaltec) (Craig, 1977), which treat S, O, and d-S the same and exclude A, e.g., relativization. Thus, in a morphologically ergative language, case marking groups S and O together and treats A differently, and in a syntactically ergative language, the restricted neutralizations treat S, O, and d-S the same and A differently. These two patterns can be represented as in Figure 3.

This difference in patterns of grammatical relations is relevant to the issue of universality. If [S, A, d-S] defines the traditional notion of subject found in English and many other languages, what is the grammatical relation defined by [S, O, d-S]? If [O] is the

traditional notion of direct object, what grammatical relation is [A]? The decomposition of grammatical relations into grammatical functions also permits a restatement of the contrast presented in Table 2, as in (17).

(17) (a) English subject [S, A, d-S]
(b) Warlpiri subject [S, A]
(c) Dyirbal 'subject' [S, O, d-S]

Both English and Dyirbal have restricted neutralizations with both intransitive and transitive verbs, hence the d-S component of subject, which Warlpiri lacks. Thus, even though the syntactic pattern in English and Warlpiri is accusative, the notion of subject is not the same in the two languages. And even though Dyirbal and Warlpiri are both morphologically ergative, they differ syntactically in terms of both pattern and types of restricted neutralizations. There are, therefore, three distinct notions of syntactic subject operative in the grammatical systems of these three languages.

The second parameter of variation among grammatical systems is the factors affecting the relations. By this is meant the factors, syntactic, semantic, or pragmatic, that affect the determination of which argument of a verb will bear which grammatical relation. That is, given the set of thematic relations associated with a multiple-argument verb, there is, in some languages, more than one possible morphosyntactic realization of these arguments. With a transitive verb in Warlpiri and the North American Siouan language Lakota (Lakhota) (Van Valin, 1977), for example, there is no variation as to which argument will be the subject and which will be the object: the actor is always the subject, and the undergoer is always the object. In these languages, the lexical semantic properties of the verb determine how the arguments will be realized; there is no variation. With a transitive verb in English and Dyirbal, on the other hand, either the actor or the undergoer may function as the subject; what conditions this choice? The fact that both roles are possible shows that the choice is not strictly semantically conditioned, as in Warlpiri and Lakhota. A major factor affecting the selection of the argument to function as subject is the pragmatic status of the argument in the discourse. It has long been noted that there is a correlation between subjecthood and topichood, and in some languages, the relative topicality of arguments affects subject choice: the most topical argument will be realized as subject, *ceteris paribus*. An analysis of subject selection in texts provides strong evidence of discourse influences on subject selection (see Van Valin, 1993). Thus, pragmatic relations of the kind discussed above play a significant role in the grammar of some languages, and in these languages, subject can be viewed as a grammaticalization of the discourse relation of topic within the clause. It is important to emphasize that although subjects appear to be highly topical in all languages that have grammatical relations, pragmatic factors influence subject selection in only some languages, e.g., English and Dyirbal. Hence, in some languages, grammatical relations represent an interaction between all three types of functional relations, and in these languages, grammatical relations cannot be considered purely syntactic.

Table 3

Construction	*Pattern*
1. 'Subject'[S, A]-triggered equi-NP-deletion	[S] only
2. 'Object'[O]-triggered equi-NP-deletion	[S, d-S(passive)] only
3. Promotion ('subject' copying with verbs like *begin*)	Dialect 1: [S] only Dialect 2: [S, d-S(both)] only
4. Relativization	[S, O, d-S(antipassive)]
5. Wh-question formation	[S, O, d-S(antipassive)]
6. Clefting	[S, O, d-S(antipassive)]
7. Cross-clause coreference (preferred)	[S, A, d-S(passive)]

The final dimension of variation is the consistency of the relations defined by restricted neutralizations. In all of the languages discussed to this point, the major constructions in the language all involve basically the same restricted neutralization. When one talks about the notion of subject in English, what is meant is that the restricted neutralization found in (7) is found in all of the major constructions in the language. Grammatical relations are thus generalizations across the consistent restricted neutralizations found in a language, and therefore consistency is a crucial feature of these relations. Not all languages have consistent systems of grammatical relations. A very extreme example of an inconsistent or split system can be found in Jacaltec, a Mayan language (Craig, 1977). Table 3, taken from Van Valin (1981), summarizes the pattern of neutralizations in seven major grammatical constructions. The inconsistency here is indeed striking: there are *five* distinct patterns in only seven constructions. It is not at all clear what 'subject in Jacaltec' in the traditional sense could mean, other than S, the only common denominator in all seven constructions. Thus, although most languages are like English, Dyirbal, and Warlpiri in having a relatively consistent system of grammatical relations, there are languages such as Jacaltec in which

there does not appear to be a set of syntactic relations that applies consistently through their grammar.

Implications for Syntactic Theories

As noted above, grammatical relations are treated differently in different syntactic theories. They play only an indirect role in GB; although reference is often made to the subject, it is always interpreted in a strictly structural way, i.e., as the NP, which is SPEC of IP or the 'external argument' of the verb. This approach crucially assumes that subject can be given the same structural definition in every language, and this is problematic. It would be possible to claim that in a syntactically ergative language like Dyirbal or Sama S and O are the external argument and A is the VP-internal argument, but phenomena like those in Jacaltec potentially pose a serious problem, since in some constructions S and O would be the external argument, in others the S alone would be external, and in yet others S and A would appear to be the external argument.

Theories like LFG and RelG, which take traditional English-like grammatical relations as basic, run into greater difficulties. The nonuniversality of grammatical relations in both senses is a significant problem. The existence of languages like Acehnese, which lack grammatical relations, is an obvious difficulty; this would appear to pose a severe challenge to the descriptive adequacy of the theories. RelG nevertheless proposes grammatical-relations-based analyses of the language (e.g., Perlmutter, 1982), though no analysis of these phenomena has yet been proposed in LFG. The variation in grammatical relations across languages is also problematic. In RelG, this has been dealt with in terms of grammatical relations at different strata in a derivation, e.g., initial versus final grammatical relations, and combinations thereof, e.g., 'working 1' = an argument that is a subject (1) in the initial stratum and a term in the final stratum (Perlmutter, 1982). Researchers in LFG have not addressed this issue, either; there are no accounts of syntactic ergativity in LFG, for example. Finally, both theories assume consistent systems of relations, and split systems like Jacaltec present another challenge. RelG approaches split systems the same way that they deal with cross-linguistic variation, namely, with formulations based on grammatical relations at different levels in a derivation and combinations thereof. An LFG account of these phenomena remains to be developed.

RRG takes a radically different approach to these problems: it rejects traditional grammatical relations as theoretical constructs and instead proposes only a single syntactic relation, which it terms 'the syntactic pivot of a construction.' Syntactic pivot is a construction-specific notion, and a pivot is defined by a restricted neutralization of the type discussed above. Thus, RRG views grammatical relations systems as being composed of syntactic pivots; languages that have the same pivot for all or most major grammatical constructions have what appears to be the traditional system of grammatical relations, but this is a derived rather than basic concept. Languages with ergative or split syntactic systems pose no particular challenge, because there is no assumption that the [S, A, d-S] accusative pivot of English is in any way the unmarked pivot universally or that a language must have the same pivot for every construction. Languages like Acehnese simply lack syntactic pivots, and grammatical constructions are characterized directly in terms of semantic functional relations. RRG integrates pragmatic relations in such a way that in languages like English and Dyirbal their influence on the determination of the pivot in a construction can be captured.

Functionalism within the Gamut of Linguistic Theories

Functionalist theories of language have most often been contrasted with formalist theories, particularly those developed by Chomsky during the past half century. This comparison is useful and will indeed form the starting point for the discussion in this article. However, like many dichotomies in linguistics, this one conceals a much more complex reality. A more realistic way of looking at things would be to posit a linear sequence of approaches, with strongly formalist theories such as Chomsky's at one end and the more radically functional approaches at the other. Even this, though, is still something of an oversimplification: what we really need is a multidimensional model in which the whole space occupied by linguistic theories is populated by groups of theories that form tighter or looser clusters according to their degree of similarity on a wide range of features. In what follows, we examine a number of features that are

Functionalist Theories of Language

C S Butler, University of Wales, Swansea, UK

© 2006 Elsevier Ltd. All rights reserved.

Functionalism within the Gamut of Linguistic Theories

Functionalist theories of language have most often been contrasted with formalist theories, particularly those developed by Chomsky during the past half century. This comparison is useful and will indeed form the starting point for the discussion in this article. However, like many dichotomies in linguistics, this one conceals a much more complex reality. A more realistic way of looking at things would be to posit a linear sequence of approaches, with strongly formalist theories such as Chomsky's at one end and the more radically functional approaches at the other. Even this, though, is still something of an oversimplification: what we really need is a multidimensional model in which the whole space occupied by linguistic theories is populated by groups of theories that form tighter or looser clusters according to their degree of similarity on a wide range of features. In what follows, we examine a number of features that are

characteristic of functionalist theories. Much more detailed discussion of many of these points can be found in Butler (2003a: Chapter 1).

A further complication that should be borne in mind as we survey the range of functionalist approaches is the distinction between European and North American functionalism. Important theories initially developed in Europe include Functional Grammar (FG: Dik, 1997a, 1997b) and Systemic Functional Grammar (SFG: Halliday, 1994; Halliday and Matthiessen, 1999, 2004). In the United States, there are two rather distinct kinds of approach: on the one hand, Role and Reference Grammar (RRG: Van Valin, 2005; Van Valin and LaPolla, 1997) belongs to the rather more formal subgroup of functionalist theories; on the other hand, there is a set of approaches, more radically functionalist in nature, that have developed out of the 'West Coast' functionalism of scholars such as Givón, Haiman, Bybee, Hopper, Thompson, DuBois, Noonan, and Goldberg and that are often included, together with Langacker's cognitive grammar, under the label of 'usage-based' models. It is important to be aware that often, in the writing of American functionalists, the labels 'functionalist' and 'functionalism' are used primarily in relation to this last group of models, often with little reference to European ideas.

The Basic Tenets of Functionalism

The three most basic principles of functionalist approaches are that

- they regard communication as the primary function of language, which shapes the forms languages take
- they attribute great importance to external (cognitive and sociocultural) factors in explaining linguistic phenomena
- they reject the claim that syntax is autonomous from semantics and pragmatics.

The most basic tenet of all, from which all others derive to some degree, is that the primary purpose of language is human communication, and that this fact is crucial in explaining why languages take the form they do. This view contrasts somewhat starkly with that of Chomsky, for whom language is essentially a vehicle for expressing thought, with interhuman communication being just one of the uses to which it can be put, and not to be prioritized over other possible functions. Chomsky (1980: 229–230) defends his position by reference to what he regards as noncommunicative uses of language, such as resolving a problem or engaging in what has been called 'phatic communion' in order simply to oil the social wheels. For the functionalist, many such situations would still be communicative, though what is communicated may be largely social or interpersonal in nature rather than purely representational. Furthermore, even if some types of language use are noncommunicative, they are, the functionalist will claim, merely parasitic upon the central communicative use.

If we are to study language as communication, then we will need to take into account the properties both of human communicators and of the situations in which linguistic communication occurs. Indeed, a further important claim of functionalism is that language systems are not self-contained with respect to such factors, and therefore autonomous from them, but rather are shaped by them and so cannot be properly explained except by reference to them. Linguists who make this claim belong to the group that Croft (1995) calls 'integrative functionalists,' and they undoubtedly form the largest and most influential group of functional theorists. The main language-external motivating factors are of two kinds: the biological endowment of human beings, including cognition and the functioning of language processing mechanisms, and the sociocultural contexts in which communication is deeply embedded. We might also expect that a functionalist approach would pay serious attention to the interaction between these factors and the ways in which languages change over time, although in practice this varies considerably from one model to another.

The question of motivation for linguistic systems is, of course, not a simple one. Much of the formalist criticism of functionalist positions has assumed a rather naïve view of functional motivation, in which some linguistic phenomenon is explicable in terms of a single factor. Functionalists, however, have never seen things this way, but rather accept that there may be competing motivations, pulling in different directions and often leading to compromise solutions.

It is important to note that formalists are not necessarily totally opposed to the claim that language is functionally motivated, although this is something that is not often discussed in the formalist literature. Newmeyer (2003a), for example, claims that even hard-line formalists would accept this claim, and that Chomsky has never denied it. The question, for Newmeyer, is how much functional motivation there is, where it is located in the system, and to what extent it should form part of the research program. In particular, Newmeyer claims that functionalists and practitioners of cognitive linguistics have

posited a tighter iconic form–function fit than is justifiable and is skeptical of the concept of competing motivations, on the grounds that anything can be explained away by some combination of such antagonistic forces (Newmeyer, 1998: 137–153, 2003b). The solution, of course, is to demonstrate such competing motivations and their antagonistic effects clearly so that functional 'explanation' does not become vacuous, a problem that is discussed in Butler (2003a: 19–25).

The great majority of functionalists also believe that within the nonautonomous linguistic system as a whole, that part of it which deals with the forms of language, and which we may call morphosyntax, is also not autonomous but is intimately bound up with the kinds of meaning that it serves to express, divided by many linguists into the semantic and the pragmatic. In other words, functionalists claim that the morphosyntax of languages is motivated by the meanings that it conveys, although we shall see that the various theories differ with regard to the strength with which they hold this position. Indeed, there are some scholars, such as Prince and Kuno, whom Croft (1995) calls 'autonomist functionalists' precisely because they do accept the autonomy hypothesis, but it can be argued that these approaches are peripheral to the mainstream of functionalism (Butler, 2003a: Chapter 1). Most functionalists would accept that there is some degree of (at least apparent) arbitrariness in the morphosyntax of any language, but many would again attempt to link this to the concept of competing motivations. The functionalist position again contrasts with the formalist one, which maintains that the morphosyntax forms a system that can be described and explained independently of meaning.

Summing up the basic characteristics of functionalist theories, we may say that the core of the functionalist position is that language systems and their components are so inextricably linked with the social, cognitive, and historical contexts of language use, and with the meanings that language is used to convey, that it is futile to attempt to describe and explain them except through reference to such factors.

Further Features

There are a number of further features that, although ultimately derivable from the basic tenets, show considerable variability across functionalist theories:

- The attempt to account for the full range of linguistic phenomena rather than merely a 'core grammar'
- The use of authentic linguistic productions as data
- Recognition and modeling of the flexibility of language in use
- Attention to discourse as well as to the sentence
- A concern with typological variation in language
- An approach to language acquisition in which the child constructs his or her language from the information available in the linguistic environment, given inherent general cognitive capacities and learning abilities

In the following sections, these points are explored in more detail.

Inclusive Rather Than Core Grammars

A truly functional approach, aiming to understand and account for language as communication, cannot restrict its scope to some kind of core grammar, as with Chomskyan theories, but must, in principle, take on the full complexity of languages and our use of them, provided, of course, that the phenomena under study are systematic.

The Use of Authentic Textual Data

If, as functionalists claim, they are interested in studying language as communication, then it is logical to assume that one of the main sources of data for their descriptions and theorizing will be samples of actual communication, in their contexts of use. In other words, we would expect functionalists to make extensive use of authentic language data in their work, particularly those large bodies of material that have been collected in the form of computer-readable corpora.

Flexibility of Meaning and Structure

If we are truly to study language in its communicative role, we must come to terms with the fact that what we say, and the way we say it, responds flexibly to the demands made by the communicative context. There are various aspects to this flexibility: the context-dependent meaning of words; the fact, clear from corpus linguistics, that a good deal of what we say is made up of reusable 'chunks' of language rather than generated or analyzed afresh every time we need to express a particular concept (*see* **Formulaic Language**); the fuzzy nature of linguistic categories, which has been modeled through recourse to the specification of prototypes; the fact that structures in actual communication are often much less rigid than the textbook grammars would allow; the emergence of grammatical categories from the requirements of

discourse; and the 'leaky' nature of the grammars we write to describe languages (Givón, 1995: 9).

A Discourse Grammar, Not Just a Sentence Grammar

Communication normally involves not just single, isolated sentences but also larger stretches of multi-propositional discourse. It follows that a truly functional theory should reflect this fact by containing not just a sentence grammar but also a model of discourse structure and of how the two interact.

Typological Orientation

Functionalists are interested not only in individual languages but also in 'language' as a whole. Since crucial motivating factors such as the human biological endowment and the overall requirements of communication are universal, we may expect that they will be reflected in linguistic universals, although it is also important to realize that because competition among motivations can be resolved in many ways, and because there are considerable differences in the sociocultural conditions under which languages are used, there are also pressures leading to diversity among languages. These concerns are manifested in the interest shown by most functionalists in linguistic typology. As pointed out by Croft (2003: 2), the label functional–typological approach is often given to an approach that seeks to motivate similarities and differences between languages in functional terms rather than in terms of the 'formal' explanations sought by Chomskyan linguists. Nevertheless, as Croft (2003: 5–6) also observes, the functionalist and formalist approaches share several fundamental characteristics, although with different emphases: both begin by analyzing language structures (functionalists in terms of function and Chomskyans in terms of formal properties), both are concerned with the central question of what constitutes a possible human language and posit universal constraints, both abstract patterns from the data (the functionalist across languages and the formalist within languages), and both explain universals in terms of universal human abilities (the functional typologist in terms of general cognitive and sociocultural abilities and the formalist in terms of innate principles specific to language).

A Constructivist Account of Acquisition

Functionalist theories, with their communication-in-context view of language, understandably tend to favor a constructivist view of language acquisition, according to which enough information is available in the linguistic environment for the child to be able to construct a grammar, with the help of more general cognitive factors and learning capacities. This is not to say that functionalists totally reject the possibility of innate characteristics: what is at issue is rather the nature of this endowment. For the functionalist, it is more likely that what is innate will be a set of general cognitive principles and predispositions to learn rather than some concrete set of linguistic rules and principles.

Important Functional Theories

This section examines briefly the European and American functionalist approaches mentioned at the beginning of this article, with particular reference to the features of functionalism discussed previously.

Functional Grammar

Functional Grammar was developed by the Dutch linguist Simon Dik and his colleagues from the late 1970s onwards. Dik made a strong commitment to the centrality, in the formulation of a grammar, of the concept of communicative function:

> The primary aim of natural languages is the establishment of interhuman communication; other aims are either secondary or derived. (Dik, 1986: 21)
>
> In the functional paradigm, . . . a language is in the first place conceptualized as an instrument for social interaction among human beings, used with the intention of establishing communicative relationships. Within this paradigm one attempts to reveal the instrumentality of language with respect to what people do and achieve with it in social interaction. (Dik, 1997a: 3)

Dik (1986) discussed in detail the kinds of external motivation that we need to appeal to in explaining why languages are as they are, also bringing in the concept of competing motivations.

Dik (1997a: 8) also rejects the thesis that syntax is autonomous from semantics and pragmatics:

> Semantics is regarded as instrumental with respect to pragmatics, and syntax as instrumental with respect to semantics. In this view there is no room for something like an 'autonomous' syntax. On the contrary, to the extent that a clear division can be made between syntax and semantics at all, syntax is there for people to be able to form complex expressions for conveying complex meanings, and such meanings are there for people to be able to communicate in subtle and differentiated ways.

He does, however, accept that grammar is a structural system, governed by a set of rules and principles, which should nevertheless be explained, wherever possible, in terms of the functioning of language as a communicative device. For example, Dik (1986: 27–28, 43) points out that expression types used to express politeness, deference, and social distance are

typically longer and more complex than less polite counterparts, and that this reflects two types of iconic principle: that of diminution vs. augmentation (important = high, big; unimportant = low, small) and the avoidance of directness (see also Haiman, 1983).

The previous quotation suggests that pragmatics, as the driver of semantics, which in turn is the driving force behind the syntax, should play an important part in FG, and Dik does indeed set up a criterion of pragmatic adequacy for his grammar. He also makes a commitment to a criterion of psychological adequacy, according to which the grammar should at least be compatible with what we know of the storage and processing of language. It has been argued, however, that Dik's work failed to live up to both of these standards of adequacy. A number of new models have been put forward under the general umbrella of FG, one of whose aims is to increase the level of pragmatic and (particularly) psychological adequacy. Particularly important among these new developments are the Functional Procedural Grammar (FPG) of Nuyts, the Functional Discourse Grammar (FDG) of Hengeveld, and the Incremental Functional Grammar (IFG) proposed by Mackenzie. Mention should also be made of the Functional Lexematic Model of Mairal Usón and colleagues, which is derived from FG and Coseriu's theory of lexematics. This model pays considerable attention to cognitive aspects of lexical structuring. Brief introductions to all these models can be found in Butler (2003a, 2003b), together with evaluations of the extent to which they, as well as the parent theory of FG, attain the standards of adequacy they aspire to.

FG and its variants are committed to providing an account of the full range of phenomena found in the world's languages rather than of some restricted core grammar. In Dik's work, most examples used to illustrate the grammar were constructed, but proponents of FG and its variants are beginning to take more seriously the need to work with authentic productions, and the use of computer-assisted corpus analysis is increasing. FG has not been among the theories that have foregrounded the flexibility of language, although there is some work on prototypes.

Dik's early model was purely a sentence grammar, although he did present a programmatic model of discourse structure in his later work (Dik, 1997b: Chapter 18). However, there have always been groups of classicists and anglicists in The Netherlands interested in the textual dimension of FG, and this interest has recently increased, with a proliferation of discourse models beginning in the 1990s. Particularly important in this connection are FDG and IFG, which aim to model discourse as well as the sentence grammar.

From its inception, FG has always had a strongly typological orientation. Dik (1997a: 14) states of FG that it should

> be *typologically adequate*, i.e., that it should be capable of providing grammars for languages of any type, while at the same time accounting in a systematic way for the similarities and differences between these languages.

This orientation is very clearly reflected in the work of Dik and other FG linguists, and it persists in recent models such as FDG and IFG.

On language acquisition, Dik (1997a: 7) states the following:

> From a functional point of view, . . . it is certainly more attractive to study the acquisition of language as it develops in communicative interaction between the maturing child and its environment, and to attribute to genetic factors only those underlying principles which cannot be explained as acquired in this interaction.

However, only a limited amount of work on acquisition has been done so far.

Role and Reference Grammar

RRG makes a strong commitment to the study of language as communication, as shown by the following quotation from an early work in which the initial basis of the theory was developed (Foley & Van Valin, 1984: 7):

> The theme underlying the various functional approaches is the belief that language must be studied in relation to its role in human communication. Language is thus viewed as a system of human communication, rather than as an infinite set of structural descriptions of sentences.

The last sentence is clearly intended to contrast the perspective taken in RRG with that of Chomskyan linguistics. With this orientation goes a concern for the functional motivation of the grammar: "RRG takes language to be a system of communicative social action, and accordingly, analyzing the communicative functions of grammatical structures plays a vital role in grammatical description and theory from this perspective" (Van Valin, 1993: 2). In practice, RRG prioritizes cognitive over sociocultural explanation, adopting what Van Valin and LaPolla (1997: 15) refer to as a 'communication-and-cognition perspective' and leaving out of account, for now, the ways in which language is used in different social situations (Van Valin and LaPolla, 1997: 3, 15).

The autonomy of syntax is firmly rejected (Van Valin, 1993: 2):

> Syntax is not autonomous. In terms of the abstract paradigmatic and syntagmatic relations that define a structural system, RRG is concerned not only with relations of co-occurrence and combination in strictly formal terms but also with semantic and pragmatic co-occurrence and combinatory relations.

In other words, RRG postulates that semantic, pragmatic, and syntactic aspects of language, and their combinations, are all crucial in explaining the observed properties of language. Syntax, however, is only relatively motivated by semantics, pragmatics, and cognitive concerns; that is, syntactic phenomena cannot just be reduced to matters of semantics and pragmatics, and there remains some arbitrariness in the formal system.

RRG aims, in principle, to provide an account of all the grammatical phenomena attested in any language. To date, it has not made extensive use of authentic data. Like FG, it does not prioritize the concept of flexibility in its account of languages. It does, however, make use of the concept of prototype, especially in its use of hierarchies of argument types to predict more and less typical choices in two areas: (1) the 'macroroles' of Actor and Undergoer in the clause, which are generalizations over more specific thematic relations, and (2) syntactic relations, which RRG conceptualizes not in terms of the usual functions of Subject and Object but, rather, in terms of the notion of the 'privileged syntactic argument' of a construction. Although RRG does offer a detailed account of a number of discourse pragmatic areas, such as information distribution (in terms of topic and focus) and switch reference, it has not developed its own model of discourse structure and is still essentially a sentence grammar.

Like FG, RRG is very much concerned with typological matters: "The theory is greatly concerned with typological issues. In particular, it seeks to uncover those facets of clause structure which are found in all human languages" (Van Valin, 1993: 4). Indeed, Van Valin says that the theory arose out of the question of what linguistic theory might look like if, rather than being centered on English, it were based on languages such as Dyirbal, Lakhota, or Tagalog.

RRG takes a constructivist line on language acquisition (Van Valin, 1993: 2):

> The RRG approach to language acquisition ... rejects the position that grammar is radically arbitrary and hence unlearnable, and maintains that it is relatively motivated (in Saussure's sense) semantically and pragmatically. Accordingly, there is sufficient information available to the child in the speech to which it is exposed to enable it to construct a grammar, and therefore the kinds of autonomous linguistic structures posited by Chomsky are unnecessary.

There have been a number of studies using RRG as a basis for accounting for observed patterns in the acquisition of morphosyntax in a variety of languages (for a summary, together with a discussion of the relationship between acquisition studies and the linguistic theory, see Butler, 2003b: 402–413).

Systemic Functional Grammar

SFG, as developed by Halliday, has its roots in the work of the British linguist J. R. Firth, with influence also from Hjelmslev, the anthropologist Malinowski, and the Prague School. Halliday makes it clear that his aim is to give an account of linguistic communication, or 'language in use,' and that languages are as they are because of the functions they have evolved to serve:

> Language has evolved to satisfy human needs; and the way it is organized is functional with respect to these needs – it is not arbitrary. A functional grammar is essentially a 'natural' grammar, in the sense that everything in it can be explained, ultimately, by reference to how language is used. (Halliday, 1994: xiii)
>
> Both the general kinds of grammatical pattern that have evolved in language, and the specific manifestations of each kind, bear a natural relation to the meanings they have evolved to express. (Halliday, 1994: xviii)

Note that Halliday takes a very strong stand on functional motivation: in principle, everything in the grammar can be motivated through function – a position that some other functionalists would regard as rather extreme. As might be expected from the antecedents of SFG in the work of Firth and Malinowski, Halliday has always been concerned more with social and cultural motivations than with those related to psychological/cognitive processes: indeed, the social dimension is more strongly developed in SFG than in any other functional theory. This is particularly apparent in the theory of social context developed by Halliday and colleagues in the 1960s and since developed not only by Halliday but also by Hasan, Martin, and others. SFG distinguishes between dialectal and diatypic (or 'register') variation in language, and within the latter between the variables of field (concerned with the nature of the social action), tenor (involving the relationships between interactants in communication), and mode (the medium of communication and its role in the linguistic event). SFG has also developed accounts of genres, seen as ways of getting things done linguistically.

SFG totally rejects the concept of an autonomous syntax. The theory is firmly centered on meaning, with syntactic patterns being seen as one mechanism for realizing meanings, a means to an end. Indeed, Halliday prefers to avoid the term 'syntax' altogether

in order to distance himself from the view that syntax can be opposed to semantics and pragmatics. Instead, he uses the term 'lexicogrammar,' chosen to emphasize the claim that grammar and lexis are not totally different kinds of patterning but are part of the same level, different in degree rather than in kind. Both act, together with intonation, to give shape to the meanings we wish to convey. Furthermore, the division between lexicogrammar and semantics is itself not a clear one: "There is no clear line between semantics and grammar, and a functional grammar is one that is pushed in the direction of the semantics" (Halliday, 1994: xix). SFG has not, historically, given high priority to typological matters, and this is reflected in the fact that the most comprehensive accounts of this theory (Halliday, 1994, 2004; Halliday and Matthiessen, 1999) are centered very firmly on English. However, currently there are signs of greater interest in typological matters (Caffarel *et al.*, 2004). The approach to typology in SFG differs sharply from that in FG and RRG in that the emphasis is on the detailed description of particular languages, followed by generalization where possible, rather than on using data from a wide range of languages in order to formulate the theory in the first place.

SFG takes a strongly constructivist line on language acquisition, and there have been longitudinal studies of three individual English-speaking children (for summaries, discussion, and references, see Butler, 2003b: 413–424).

We should note here the existence of a second version of SFG, developed by Fawcett and colleagues. This model takes Halliday's work as its starting point but modifies it in a number of important ways, one of which is to propose clearly separate levels of semantics and syntax (Fawcett, 2000). However, this version still treats the semantics as the underlying driving force at the center of the model, with syntax as one means (together with lexical items and intonation) for the realization of meaning.

West Coast Functionalism

So-called West Coast functional grammar was never a single, unified model but, rather, a fairly loose collection of individual approaches. We cannot, therefore, survey the whole area here but will concentrate on one important exemplar, the work of Givón.

Givón subscribes fully to the central tenets of functionalism discussed previously. He (1995: xv) holds that "language (and grammar) can be neither described nor explained adequately as an autonomous system," but that in order to understand why language is as it is, we must make reference to "the natural parameters that shape language and grammar: cognition and communication, the brain and language processing, social interaction and culture, change and variation, acquisition and evolution." It is, however, possible for competing motivations to lead to a situation in which grammar "assumes its own reality" (Givón, 1995: 11). The central part played by semantics, pragmatics, and discourse within Givón's approach to language is abundantly clear in all his work. Furthermore, relationships between linguistic usage, synchronic variation, and language change are discussed in terms of the grammaticalization of originally lexical elements.

Givón rejects Chomsky's sanitization of the data for linguistic theory building, through the prioritization of competence over performance. He thus takes an inclusive stance on the range of phenomena for linguistic study, and makes frequent use of attested linguistic data, especially in his studies of the frequency distribution of features in different languages and their varieties. Although Givón does not offer a model of discourse structure as such, his work is very much involved with the relationship between grammar and discourse, and context is a key concept in his work. The flexibility of language is an important theme in Givón's writing, and the concept of prototype is central.

Givón's work is strongly typological in nature, striking a balance between what is common across languages and their individual characteristics. He (1995: 17) comments that "[w]hile recognizing cross-language typological diversity, most functionalists remain committed to the existence of language universals, presumably both of meaning/function and grammatical structure."

Finally, Givón takes an explicitly constructivist position on language acquisition, claiming that what the child initially acquires is not syntax, in the Chomskyan sense, but rather a more rudimentary communicative system, which only later becomes modified toward syntax. He castigates Chomsky for his rejection of communicative function, general cognitive capacities, and sociocultural effects as important factors in acquisition.

Usage-Based Functionalist–Cognitive Models

The label usage-based is used for a group of models that claim that "the speaker's linguistic system is fundamentally grounded in 'usage events': instances of a speaker's producing and understanding language" (Kemmer and Barlow, 2000: viii). This label brings together models derived from earlier work in West Coast functionalism with approaches such as Langacker's cognitive grammar and some variants of construction grammar, such as Goldberg's model. Here,

we concentrate on those approaches that derive from the earlier work of West Coast functionalists.

One important strand of usage-based functional linguistics is Hopper's Emergent Grammar, which takes a very radically functionalist stand in claiming that "[g]rammar . . . is not the source of understanding and communication, but a by-product of it. Grammar is, in other words, epiphenomenal" (Hopper, 1998: 156). Thus, a grammar is seen not as a unified, relatively stable system but, rather, as "an open-ended collection of forms that are constantly being restructured and resemanticized during actual use" (Hopper, 1998: 159). This model is thus firmly rooted in the communicative functions of language and in the cognitive and social contexts of language use. It also pays great attention to relationships between usage, synchronic variation, and diachronic change, through the study of grammaticalization.

Closely related to emergentism is work by Thompson, Hopper, Bybee, and others, which prioritizes the study of authentic conversational data, and in which the concept of broad syntactic templates is replaced by local, lexically bound schemas or collocations, often formulaic in nature, which are specific to the language concerned. These reusable fragments, often with slots for variable items, are seen as empirically verifiable instantiations of the concept of construction, seen as a pairing of form and meaning/function, which is central to construction grammar models. For instance, Thompson (2002) presents evidence that in conversational English what are traditionally analyzed as complement-taking predicates (e.g., *think* + complement clause) are better seen in terms of the combination of (1) a fragment, often formulaic in nature, with epistemic, evidential, or evaluative function, such as *I think/I don't think/I thought/ I didn't think/I guess/I remember*, etc., and (ii) a declarative or interrogative clause that carries the main representational content.

Clearly, these usage-based approaches adopt a very inclusive stance on the range of phenomena that are to be accounted for, since the basic aim is to provide an explanatory treatment of the rich diversity to be found in authentic interaction. These models are very much concerned with the flexible responses of language to the contexts in which it is used: they are rooted in the discourse and the ways in which it conditions the choice of what is said and how it is expressed. Considerable weight is given to the frequency of particular items and combinations in language use, on the grounds that frequency demonstrably affects a range of phenomena, including phonological reduction, constituent structure, and the retaining of irregular or even archaic patterns (Bybee and Hopper, 2001). Typological data are also crucial and are taken to support the paramount importance given to discourse motivations for grammatical structuring. Finally, a clearly constructivist line is taken with respect to language acquisition (Tomasello, 2003).

Conclusions

Functionalism, like other terms for 'schools' of linguistics, is a convenient label for a complex, varied set of approaches to linguistic theory and description. We have seen, however, that these approaches are united by rejection of the claim that the linguistic system should be studied independently of the cognitive, sociocultural, and temporal factors that at least partially motivate it and also by rejection of the claim that syntax is autonomous from semantics and pragmatics. Functional models regard language as primarily a means for human communication in context and attempt to explain as much as possible in terms of functional motivations, which may compete to give the appearance of arbitrariness in the system. Many also exhibit a number of derived characteristics, although these are much more variable across models: They are not confined to a core grammar but, rather, attempt to take on board the full range of systematic linguistic phenomena; they often use authentic linguistic productions as part of their database; they attempt to model the flexibility and 'fuzziness' of language; they are concerned with discourse as well as the sentence grammar; they study typological variation in language; and they adopt a constructivist approach to the acquisition of language by the child.

Finally, it is important to note that there are important similarities between functional models, as defined here, and explicitly cognitively oriented approaches such as Cognitive Grammar and the various models of Construction Grammar. This is reflected, for example, in the fact that recent usage-based models embrace both functional and cognitive orientations (see also Horie and Comrie, 2000).

Future Tense and Future Time Reference

Ö Dahl, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

It is tempting to think of time simply as a line extending in both directions from the point at which we happen to be located. However, in constructing a theory of temporal semantics, we have to acknowledge that what is ahead of us – the future – is epistemologically radically different from both what is behind us – the past – and what is taking place at this moment – the present. Future states of affairs cannot be perceived or remembered, although they can be the subject of our hopes, plans, conjectures, and predictions. Philosophers such as Aristotle have claimed that the future has a special nature not only epistemologically but also ontologically: statements about the future do not yet have a determinate truth value. In a possible worlds framework, the 'branching futures model' can be seen as an expression of a similar idea: time looks like a tree rather than a line, and at any point in the tree there is only one way back into the past, but many branches lead into the future.

Against this background, it is perhaps not so strange that there tend to be asymmetries in the ways in which temporal reference is structured in

Future Tense and Future Time Reference

Ö Dahl, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

It is tempting to think of time simply as a line extending in both directions from the point at which we happen to be located. However, in constructing a theory of temporal semantics, we have to acknowledge that what is ahead of us – the future – is epistemologically radically different from both what is behind us – the past – and what is taking place at this moment – the present. Future states of affairs cannot be perceived or remembered, although they can be the subject of our hopes, plans, conjectures, and predictions. Philosophers such as Aristotle have claimed that the future has a special nature not only epistemologically but also ontologically: statements about the future do not yet have a determinate truth value. In a possible worlds framework, the 'branching futures model' can be seen as an expression of a similar idea: time looks like a tree rather than a line, and at any point in the tree there is only one way back into the past, but many branches lead into the future.

Against this background, it is perhaps not so strange that there tend to be asymmetries in the ways in which temporal reference is structured in

languages, and that in particular the grammatical category of tense often blurs into modality and evidentiality in the area of the future. Whether for instance the English auxiliaries *shall* and *will* should be seen as markers of future tense or rather as ordinary modal verbs is a much-debated issue, the importance of which depends on the stand one takes on another, equally contentious, issue: how essential it is to uphold the discreteness of grammatical categories. If it is acknowledged that it is normal for the semantics of grammatical items to combine temporal elements with components of a modal, evidential, or aspectual character, it may become more important to study how the weight of these different factors shift over time, in the process of grammaticalization. From this perspective, it is notable that the diachronic sources of what grammars refer to as future tenses typically have exclusively nontemporal meanings, and the temporal meaning elements tend to grow stronger during the course of grammaticalization ('temporalization,' in the term of Fleischman, 1983), as future markers gradually obtain an obligatory status. English is a language that has advanced relatively far along the road towards obligatory marking of future time reference. In this regard, it is instructive to compare English to a language such as Finnish, in which there is hardly any grammaticalization of future time reference. In English, the sentence *It is cold tomorrow*, with the present tense of the copula *is*, sounds rather strange: it is more natural to say *it will (it'll) be cold tomorrow* or *it is going to be cold tomorrow.* In Finnish, on the other hand, we may replace the adverb *tänään* 'today' in the sentence *Tänään on kylmää* 'Today is cold' with *huomenna* 'tomorrow,' yielding *Huomenna on kylmää* '(lit.) Tomorrow is cold,' without any further changes in the sentence. Thus, Finnish weather forecasts are typically formulated in the present tense, which is hardly possible in English.

The English examples, however, also illustrate two other important points. First, the obligatoriness of future marking in English is not independent of the epistemological status of the statement. If it concerns an event that is fixed by some kind of schedule, English tends to use the present tense, although the time referred to is in the future, as in *The train leaves at noon.* Second, future marking is an area where we often find competition between two or more grammatical devices. For English, *will* and *be going to* have already been mentioned, but there are in fact several additional ways of referring to the future, such as by the present progressive (*We are leaving at four*) or by a combination of *will* and the progressive (*The shop will be closing in five minutes*), neither of which have a progressive meaning in the examples cited. Other languages are similar: Bybee *et al.* (1994) found at least two futures in 70% of the languages in their sample and at least three in close to 25%. As the word 'competition' suggests, the choice between the alternative ways of marking future is usually not reducible to any simple semantic or pragmatic distinction: rather, a number of different factors are at play: thus, *will* and *be going to* differ both semantically and stylistically. In many cases, differences between future-marking devices are attributable to what point they have reached in the grammaticalization process; in others, the differences reflect the original meanings of the diachronic sources of the items in question.

Future-marking devices derive historically from a number of sources. Among the most common are auxiliary constructions expressing obligation ('must'), e.g., English *shall*; volition/intention ('want'), e.g., English *will*; and motion ('go' and 'come'), e.g., English *be going to*. However, a future tense may develop out of an earlier nonpast or imperfective as an indirect effect, for example of the expansion of an earlier progressive – the future uses are what is left of the old category after that expansion (possible examples mentioned by Bybee *et al.* (1994) are Margi, Tigre, Pangasinan, and Kui).

In the development of futures, several things happen. To start with, there is normally an initial change of meaning that may involve both what has been called 'pragmatic strengthening' and 'semantic bleaching.' Thus, a verb of volition, such as *want*, does not normally imply that the willed action is performed; to interpret something like *She wants to leave* as 'She will leave,' the meaning of the volitional verb has to be strengthened. But when extended to cases of 'pure prediction' such as *It will rain,* the volitional element has to be bleached altogether. Furthermore, the item gradually comes to be used in contexts where it is communicatively redundant, which leads to it being reduced phonetically (e.g., *is going to* > *is gonna*). Eventually, the grammaticalizing item may fuse with the main verb and become affixed to it. A famous example is the French inflectional future as in *il chantera* 'he will sing,' which derives from a construction involving the Latin verb *habere* 'have' in an obligative meaning. English *shall/will* have not become inflections, although they are usually cliticized to the preceding word in the reduced form *'ll*.

Being usually more advanced on the grammaticalization path, inflectional futures tend to have a wider range of uses than periphrastic ones. Normally, future-marking devices start out in main clauses, which are bearers of the illocutionary force of an utterance. English is an example of a language in

which no future time marking is normally found in some types of subordinate clauses, such as conditionals and temporal clauses – for example, *If it rains, you'll get wet*, where only the main clause is marked for future time reference. As it turns out, future marking in such clauses tends to be restricted to languages with inflectional futures (Bybee and Dahl, 1989).

It was said above that future states of affairs are the subjects of our hopes, plans, conjectures, and predictions. The latter notions also represent what we can call different epistemological bases for statements about the future, and, as was also mentioned above, the way in which such statements are expressed in a language can depend on which kind of epistemological base it has. A major distinction may be drawn between **intention-based** and **prediction-based** future time reference. Particularly in everyday conversation, a large part of what is said about the future refers to plans and intentions of the participants. I announce what I intend to do, or ask you what you intend to do. This is clearly different from discussing what the weather will be like tomorrow. A straightforward grammatical opposition based on the distinction between intention-based and prediction-based future time reference is less common than one would perhaps think, in view of the apparent cognitive salience of that distinction. Its importance lies rather in the observation that markers that are originally restricted to intention-based future time reference tend to develop into general future markers, which include prediction-based future time reference as central cases but can in the normal case still be used for intention-based future time reference.

Another major parameter is the temporal distance between the speech act and the future time point in the future. Immediacy is often cited as a condition on the use of certain future-marking devices, such as the English *be going to* or the French *aller* + infinitive construction. At a closer look, it often turns out that immediacy is a contributing factor but hardly the only one, as we shall illustrate below. It does happen, however, that more precise restrictions on temporal distance develop, although this is much less common for the future than for the past. Bybee *et al.* (1994) cite Mwera (1994; original source Harries, 1950) as an example of a language that has three different future auxiliaries, *ci* for reference to the same day (hodiernal future), *cika* for the following day (crastinal future), and *jiya*, which they interpret as a general future.

Typological surveys (Dahl, 1985; Bybee, 1994) have shown approximately equal numbers of inflectional and periphrastically expressed futures. In the sample in Dahl and Velupillai (2005), North America, Australia, central New Guinea, the Caucasus, and South Asia come out as areas where languages with inflectional futures are in a clear majority. Among areas where inflectional futures tend to be absent are Southeast Asia (where most languages are isolating) and northern Europe.

G

Gabelentz, H. Georg Conon von der (1840–1893)

K R Jankowsky, Georgetown University, Washington, D.C., USA

© 2006 Elsevier Ltd. All rights reserved.

Hans Georg Conon von der Gabelentz, born March 16, 1840, in Poschwitz, Germany, studied law, Asian languages, and comparative linguistics at the universities of Jena and Leipzig. After graduation in 1863, he served for 12 years as an employee of the Royal Saxonian government in Dresden, Leipzig, and Strassburg. In 1876, immediately upon earning a doctorate from Leipzig University with a thesis on the Chinese philosopher Zhou Dunyi, he applied for a professorship of Chinese, Japanese, and Manchurian. With a great deal of good luck and the strong support of the well-established Sinologist Wilhelm Schott (1807–1889), Gabelentz was appointed Professor Extra-ordinarius for East Asian languages in 1878 and 4 years later, in Leipzig, became the occupant of the first Chair at a German University in East Asian Studies. The last 4 years of his life, he taught at Berlin University as Ordinarius für Sinologie und allgemeine Sprachwissenschaft.

During the last two decades of the 19th century, Leipzig University enjoyed an unprecedented reputation as the center of the new historical linguistic studies, with the Neogrammarians, a group of young and highly productive Germanists and Indo-Europeanists, being the undisputable leaders in the field. From the very beginning, Gabelentz found himself in a difficult position. In comparison to Indo-European languages, his specialty was rather marginal, with only a very small number of students attending his lectures. More importantly, his approach to language study was on at least two counts markedly different from that of the Neogrammarians. Taking his lead from Wilhelm von Humboldt's linguistic philosophy, Gabelentz saw language as a system where inner and outer forms exist in a relationship of mutual interdependence. He therefore moved away from the Neogrammarians' almost exclusive emphasis on outer form and at the same time focused on synchronic rather than diachronic language study. He studiously avoided controversy, yet this only made it easier for 'mainstream linguistics' to treat him with disregard. Hermann Paul (e.g., 1920: 125) mentioned him repeatedly and approvingly, but there was no other substantive reaction to his work from the Neogrammarian group. Outside Germany, on the other hand, Gabelentz's ideas caught on much earlier than in his native country. The Czech linguist Vilém Mathesius (1882–1945), as well as the Danish linguists Otto Jespersen (1860–1943) and Louis Hjelmslev (1899–1965), acknowledged their indebtedness to various aspects of Gabelentz's approach. In Germany, it was Eugenio Coseriu (1921–2002) who in 1969 led the way to a comprehensive recognition of what Gabelentz had contributed to the development of general linguistics (cf. Gabelentz, 1891). Through Coseriu's elaborate investigation, it became apparent that Gabelentz had developed, and worked with, numerous ideas of groundbreaking importance for linguistic science, e.g., the differentiation between language use (*Rede*) and language system (*Sprache*), a distinction crucial for Saussure and, subsequently, for 20th-century structuralism.

Gabelentz was primarily interested in East Asian languages. His "great grammar [1881] is even today indispensable for the study of the Chinese written language" (Richter, 1979: 30). In the preface to the 1960 edition, Eduard Erkes stressed that "it is undoubtedly quite unusual for a scholarly work to experience a new unchanged edition after 70 years" (vii). Among the 105 books and articles and more than 200 reviews listed in Richter (1979) are numerous other publications dealing with East Asian languages and culture (e.g., 1882, 1888a, 1888b). But Gabelentz had a much wider range of interest and expertise, encompassing, e.g., the analysis of Basque and certain North African languages (1893, 1894) and even venturing into exploring the area of native American languages (see Richter, 1979: 34).

His early death (December 11, 1893, Berlin) cut short a life still full of now irretrievable promise.

Gabon: Language Situation

L J Van der Veen, Dynamique du Langage Research Laboratory, Lyon, France

© 2006 Elsevier Ltd. All rights reserved.

Since its adoption as official language by the Republic of Gabon in 1960, French has been used for education and official written communication, economic and financial activities, and politics and administration. It is now rapidly expanding among younger generations to other domains of social exchange as everyday communication, especially in urban contexts. Perceived as synonymous with access to employment, welfare, and the outer world, it is presently used by 70 to 75% of Gabon's inhabitants. According to the latest Ethnologue report, French literacy rate amounts to approximately 75%. The total number of Francophones is steadily growing and the quality of mastery is globally improving.

French is becoming the first acquired language for an increasing number of children. However, due to social, educational, and geographical differences, there is some disparity in the degree of mastery and actual practice. French is only occasionally used, for instance, in less developed rural non-institutional environments, where the vernacular languages still play a significant role. A decreasing number of Gabonese, generally older generations who learned French in non-institutional contexts, speak local varieties of French, mainly characterized by lexical traits. (Boucher and Lafage (2001).)

Recent attempts made by the Raponda-Walker Foundation to introduce vernacular languages into the educational system have not been very successful due to organizational, scientific, and political reasons. Gabon's complex ethnic situation is a potential source of conflict. In response to this, the official language policy is to reinforce the use of French, as it constitutes a unifying factor in a multilingual space, and to improve or replace the often out-of-date methods used for teaching French.

Multilingualism is omnipresent. Most Gabonese speak one or more local languages besides French, including their mother tongue. Code-switching is a well-attested phenomenon, especially among young people: lexical and grammatical French items appear within local language utterances in a more or less principled manner.

French is gradually replacing the vernacular languages, which are increasingly exclusive to in-group communication. Massive borrowing from French is current; its generalized use constitutes a serious threat to the vernacular minority languages.

In close collaboration with linguists from the MRAC (Tervuren, Belgium) and the Omar Bongo University (Libreville), a team of Bantuists of the Lyon 2 university have substantially contributed over the last 25 years to the understanding of the

overall linguistic situation of Gabon and the description of the individual local languages. Extensive on-site sociolinguistic inquiries and surveys have nourished synchronic and diachronic descriptions, and generated numerous scholarly publications. Today the overall linguistic situation is much clearer than two decades ago, though more in-depth investigation is needed.

Inventory of Language Varieties

Table 1 presents a detailed inventory of the Bantu and Pygmy language varieties of Gabon. Some of these vernacular languages, e.g., Fang, may be used for communication between members of different ethnic groups, especially in non-urban environments. The language references used in Table 1 are from Maho, 2003, based on those elaborated by Malcolm Guthrie. The precise status of some newly added varieties remains to be determined. The sources of the date appear after each estimated number of speakers. Demographic data have been taken either from Ethnologue (abbreviated in the table as Ethn.) or the official 1993 census of the Gabonese population (abbreviated OC93). Minor language varieties are often not visible in the census, because they are included, sometimes in a somewhat arbitrary way, in one of the major ethnolinguistic groups. No separate estimations (abbreviated NSE) are available for most of these languages. Ethnologue language names are included parenthetically if they are different from the names used here. An asterisk indicates that a language is absent from the Ethnologue database.

Localization of Language Varieties

The speakers of the varieties listed in Table 1 are distributed all over the country; for locations, see the map in Figure 1. Most of the local ethnolinguistic communities are represented in Libreville. Members of these groups generally live together in separate districts of the capital (see Kwenzi-Mikala, 1992). Other urban centers also attest to a great variety of local populations.

The map indicates the geographic locations of most of the language varieties listed in Table 1. Its scale, however, does not allow much accuracy as to their precise locations; moreover, we have no location information for some minor language varieties. Most villages are situated along the main communication axes; villages and people often move along these roads and rivers. Several regions, mostly heavily forested, are uninhabited.

Small Pygmy settlements are found in all provinces, nearly always at the fringes of the forest, in the vicinity of their Bantu neighbors with whom the Pygmies frequently interact. Their genetic affiliation is uncertain. The Pygmies are generally considered to have been in place before the arrival of Bantu-speaking groups. Formerly hunter-gatherers, today they have a semi-nomadic lifestyle, partially due to government policy. The Baka(o) live in the extreme north, the Koya in the northeast, the Bongo in the more central and southern regions, and Okoa in the estuary. The Rimba and Gama live in the southwestern part of Gabon. According to Mayer (1987), basically three types of situations exist; the first of these is by far the most common:

1. Pygmies who speak the same language variety as their Bantu neighbors, with no traces of some original language (e.g., the Koya in the Mekambo region);
2. Pygmies who speak some mixed Bantu language resulting from extensive but eclectic borrowings not matching any specific Bantu variety (e.g., the Bongo near Mbigou);
3. Pygmies who speak a non-Bantu language in a Bantu environment, but who are completely bilingual (e.g., the Baka speak an Ubangian language as their mother tongue in a Fang environment, but use Fang for everyday communication).

Most language varieties spoken by the Pygmies are not mutually intelligible.

Issues Related to Classification

The Bantu varieties of Gabon can be grouped into a dozen clusters (Table 1) belonging to three different but contiguous geolinguistic zones (A, B, and H). Table 2 presents classification issues and some specific linguistic traits.

The Bantu languages of Gabon belong to what is now called Forest Bantu, which is a part of Western Bantu, as opposed to West-central Bantu and Eastern Bantu (Nurse and Philippson, 2003). For Bastin *et al.* (1999), zone A languages constitute, together with B10–B20–B30, Northwestern Bantu opposed to the rest of the western languages. This implies the presence of a linguistic barrier within Gabon, and especially within zone B (see Figure 1).

On the basis of several structural innovations, at least four higher-level clusters may be established: A (including *A75*), *B10–30*, *B50?–60–70*, parts of B80–H24, *H10*–30, H42, *B40*–parts of B85 (groups attested in Gabon are in italics.) The precise articulations between these higher-level clusters are still being examined.

Table 1 Inventory of vernacular languages spoken in Gabon

Present and Future Status

The vernacular languages, none of which has received any official status, play an important role in the perpetuation of traditional practices and beliefs. They may be freely used for these purposes. However, many of these varieties are seriously threatened by extinction within two or three generations. Several languages are in the course of being abandoned. The impact of French reinforces this demise, as does the rural exodus.

As a consequence of multilingualism and convergence, several languages present clear signs of admixture. Viya's affiliation with B30, for instance, is beyond doubt, but subdomains of its lexicon reveal signs of extensive borrowing from neighboring Shira (B41). The Makina people speak Shiwa (A83), but their language and culture is today yielding to the fast-growing influence of Fang (A75). Shiwa speakers now generally speak Fang and are abandoning their language.

The conservation of the linguistic and cultural heritage of Gabon is a matter of utmost emergency. Special, though insufficient, efforts are being made in order to save as much of the linguistic patrimony (i.e., the remaining languages) as possible. Linguists from Libreville and Lyon are preparing a detailed atlas of the languages and ethnic groups of Gabon. Recently, two scientific dictionaries have become available: Van der Veen and Bodinga-bwa-Bodinga (2002) concerning Viya, and Mickala-Manfoumbi (2004) on Vove.

Peopling of the Gabon Area

On the basis of the available linguistic data, historical inferences can be made about the peopling of the Ogooué-Ivindo-Ngounié area by Bantu-speaking populations. Successive waves moved away from a major western Bantu expansion, which originated in northwestern Cameroon and spread southward. Some linguistic groups of Gabon migrated from more northern regions (Myene-Tsogo, and much later, Fang),

Figure 1 Localization of vernacular languages in space. Pygmy settlements according to Mayer (1987).

others from southern regions (Shira-Vili), and others from regions located to the east (Njabi-Mbaama-Teke) (see Figure 2).

The chronology can only be very approximate; linguistic data roughly matches the available archaeological data. The first Bantu-speaking populations must have arrived around 1000 B.C. or earlier (with the spread of agriculture), whereas the Fang migration did not occur until the 17th through 20th centuries A.D.

Comparative studies suggest an ancient affiliation between the Myene and Tsogo groups, but there must have been a convergence between B10 and part of B30 at a later stage, after their initial separation. At an even higher level, B10–B30 clusters with zone A languages, as an ancient branch of Western Bantu (Bastin *et al.*, 1999; Mouguiama-Daouda and Van der Veen, forthcoming, due in 2005). B20's precise affiliation is still a matter of debate, but there is evidence of an ancient genetic relationship between this group and A34. Some uncertainty also exists concerning the genetic affiliation of all or part of B50. Oral tradition claims the Njabi speakers migrated from Democratic Republic of Congo. B50 is generally considered related to B60–B70–B80 (the latter in DRC), but the observed clustering may also be the result of a prolonged hybridization. Some scholars suggest an ancient affiliation with B20. Vili speakers (H12a) claim a southern origin, as do most of the B40 speakers. Linguistic data corroborates this claim. A preliminary study of Baka lexicon suggests several

Table 2 Classification issues and specific linguistic traits

Group	*Classification issues*	*Specific traits*
Benga	Ancient affiliation with B20?	7V system. Glottal fricative. No spirantization.
Fang	Northern and southern subgroup; varieties attesting traits from both	Frequent loss of final vowels with consequences for syllable structure, vowels, and tone. 8V. Diphthongs. Labiovelars. Signs of spirantization and merger of high and mid-high vowels in southern dialects. Synopsis: Medjo Mvé, 1997; Mba-Nkoghe, 2001
Bekwil	Dialect cluster (Gabon, Congo-Brazzaville, Cameroon)	7V. Closed next to open syllables. Distinctive vowel length. Diphthongs. Very close mid-high vowels. Labiovelars. Outline: Bouka, 1995
Myene	Closely related varieties Relatively recent linguistic diversification?	Consonantal alternations in base-initial position. 7V. Traces of fossilized augments and of Meinhof's rule. Profoundly altered tone systems. Def. vs. Indef. contrast expressed by tone. Nasalized labial approximant in B11a. Synopsis: Mouguiama-Daouda & Van der Veen (forthcoming, due in 2005)
Kele	Geographically (see map) and linguistically, most divergent group. Ancient diversification? Floating group in most recent classifications (cf. Bastin *et al.* 1999). Clusters with A + B10 – B30 or with other, more southern groups. Two major subgroups: Kota cluster and Kele cluster. B22c (''Bubi'') affiliates with B30 (Jacquot, 1983 and Van der Veen, 2003	Under examination. 7V. Weakening or loss of final vowels in several varieties, e.g., B22a Nasalization of vowels due to loss of nasals. Glottal fricative in several varieties, e.g., B252 Frequently -ak- suffix in infinitives Spirantization emerging in several languages: B203, B204, B22a, B25, B251
Tsogo	Dialects Kande, Pinzi, Himba form northern subgroup (with considerable influence from B10). Other varieties: separate, though related languages. Increasing pressure on Viya and Vove from surrounding non-B30 languages	7V. FUT: -nga-. Absence of noun class 15 and traces of 10. 19/13 pairing Vove: very close mid-high vowels Synopsis: Van der Veen, 2003
Shira	Rather homogeneous group, several varieties are dialects. Morphology, tonology, and lexicon suggest clear genetic relationship between B40 and part of H10	5V. Distinctive vowel length. Spirantization. Tone cases: Blanchon, 1999. Overview B40–H10: Blanchon, 2000; Idiata-Mayombo, 1998
Njabi	Closely related varieties	Nzebi, Wandji, and other varieties have 7 (phonemic) vowels in C_1 (though not directly related to the 7V of proto-Bantu) and 5V in C_2. Spirantization. More detailed studies: Hombert & Mouele, 1988; Marchal-Nasse 1989; Blanchon, 1987
Mbaama	Three major varieties: Mbaama (7V), Kaningi (7V + phonemic length) and Ndumu (5V) Mbete (B61): dialect of Mbaama. Ndumu: four dialects (see **Table 1**). Members of B60 undergo pressure from B50 and B70	Spirantization: pf and bv. Flap
Teke	Represented in Gabon by two varieties (acc. to Jacquot (1978)). Most of Tege is spoken in DRC and Congo Tsaayi: extinct in Gabon at present?	5V. Distinctive vowel length. Nasalized vowels in some dialects due to the loss of nasal consonants (Hombert, 1986). Spirantization (Fontaney, 1984)
Kongo	Represented in Gabon by Vili. Other varieties spoken in Congo-Brazzaville	H12a and B40 share structural features: 5V, tone cases, spirantization, etc. Overview of B40–H40: Blanchon, 2000
Baka-Gundi	Baka: Ubangian language variety. Probably related to language spoken by Baka populations in Cameroon and DRC	No noun classes 7V. Complex tone system Sound inventory similar to nearby Bantu. Recent and ancient loanwords from several contiguous and noncontiguous Bantu languages (mainly A75, B10, B20, B30

periods of contact with Bantu speakers at different stages of time and place. This ongoing study may provide further indications as to the expansion patterns of languages such as Myene, Kele, and Tsogo.

Several of the above-mentioned hypotheses have recently been submitted to geneticists for examination. Blood samples have been collected from some 950 individuals belonging to 21 ethnolinguistic groups. Will population genetics corroborate the linguistically based inferences? Issues such as affiliation, homoplasy (convergence due to contact), geographic origin (e.g., Fang), expansion routes, and impact of

Figure 2 Major Bantu expansion routes in the Gabon area. The routes have been inferred from diachronic language studies; successive waves move away from the main western expansion at different stages in time: (1) Western Bantu expansion originated in northwestern Cameroon (approx. 5000 B.P.). (2) Myene-Tsogo branch, perhaps with Kele. (3) Shira-Vili split off. (4) Njabi(?)-Mbete-Teke branch. (5) Fang expansion (started in 16th century A.D.). Reference numbers taken from Maho, 2003.

mating patterns are being studied carefully. This multidisciplinary approach, which also brings in cultural anthropology and archaeology, offers new perspectives. Results regarding mitochondrial DNA and Y-chromosome variation will become available in 2005, when it will be examined by specialists from all involved disciplines. For a detailed presentation of this project, see Van der Veen *et al.* (forthcoming, due in 2005).

Gadamer, Hans-Georg (1900–2002)

G Moretti, Rome, Italy

© 2006 Elsevier Ltd. All rights reserved.

In 1979, while reflecting upon the philosophical relationship that for decades had united Hans-Georg Gadamer and Martin Heidegger, J. Habermas used an interesting expression. He remarked that Gadamer "had urbanized Heidegger's provinces." Gadamer studied under Heidegger (see Heidegger, Martin [1889–1976]) in Marburg, a German university town where Heidegger, 11 years his senior, taught for a short time (it was the 1920s, a difficult time for the German economy). During this brief period, the young Gadamer experienced a life-altering crisis that would transform the course of his existence (as well as that of other future important German philosophers).

Gadamer's notion of *Wirkungsgeschichte,* or "effective history," which the philosopher often referred to in his writings, represents the principle of 'urbanization.' As particularly evident in his most important work, *Wahrheit und Methode* (1960), this notion has been successful in drawing closer together those authors and philosophical schools of thought about whom Heidegger had spoken in radical and inflexible terms, for example, Plato, Hegel, and the humanists in general. Heidegger had, in fact, come to reject the very connotation of 'tradition,' regarded in its highest terms, to which Gadamer, in contract, paid the utmost attention. Gadamer succeeded in leading

Gadamer, Hans-Georg (1900–2002)

G Moretti, Rome, Italy

© 2006 Elsevier Ltd. All rights reserved.

In 1979, while reflecting upon the philosophical relationship that for decades had united Hans-Georg Gadamer and Martin Heidegger, J. Habermas used an interesting expression. He remarked that Gadamer "had urbanized Heidegger's provinces." Gadamer studied under Heidegger (see Heidegger, Martin [1889–1976]) in Marburg, a German university town where Heidegger, 11 years his senior, taught for a short time (it was the 1920s, a difficult time for the German economy). During this brief period, the young Gadamer experienced a life-altering crisis that would transform the course of his existence (as well as that of other future important German philosophers).

Gadamer's notion of *Wirkungsgeschichte,* or "effective history," which the philosopher often referred to in his writings, represents the principle of 'urbanization.' As particularly evident in his most important work, *Wahrheit und Methode* (1960), this notion has been successful in drawing closer together those authors and philosophical schools of thought about whom Heidegger had spoken in radical and inflexible terms, for example, Plato, Hegel, and the humanists in general. Heidegger had, in fact, come to reject the very connotation of 'tradition,' regarded in its highest terms, to which Gadamer, in contract, paid the utmost attention. Gadamer succeeded in leading

Heidegger away from the 'provinces' in which he had confined his thought and toward the vastness of the 'philosophical metropolis' and a constant discourse with tradition. The theory of philosophical hermeneutics, which emerged as a result, tries to weave the threads of human knowledge, a knowledge of which philosophy is the depositary, although not the sole one, in spite of the real and dramatic historical 'cuts' that have occurred.

Gadamer therefore distanced himself from Dilthey's belief in a distinction between natural sciences and human sciences; this eventually led him to confine their historical comprehension to an almost museum-like dimension. Gadamer's theory of understanding (*Verstehen*) is the reaffirmation of how vitally important it is for the human being to be involved with the object of his studies, also scientific.

Philosophical hermeneutics (see Habermas, Jürgen [b. 1929]) does not seek to assume a sort of epistemological role somehow superior to the theories subtending scientific knowledge. It is, rather, the close examination of the 'preunderstanding' horizon common to every human cultural event or action (hence, Gadamer's discussion of 'prejudice'). Consequently, Gadamer's *Verstehen* characterizes the relationships among human beings that existed prior to the onset of any scientific knowledge, revealing itself as a sort of existential substratum for man. By virtue of this substratum, understanding can effectively be regarded as value, that is, also as a result of 'effects.' This value uses language as its own preferred and indispensable *medium*, to the point of binding permanently together, according to Gadamer, understanding and interpretation as linguistic events. His concept of 'reason' is aimed at recovering the omnicomprehensive dimension that in the Platonic era had never been considered in abstract terms, as if disconnected from the realm of human action. According to Gadamer, reason must always be ruled by reasonability and wisdom. This is the *Phronesis*. Human language, handed down to us from history, is the medium that enables us to hold together both past and future dimensions in a present that is "reasonable and active."

Poetry holds a special place in Gadamer's thought, as in Heidegger's, by virtue of his firm belief in the privileged relationship that links it with the phenomenon of language. In addition to German classical poets such as Hölderlin, Goethe, and Schiller, he dedicated an important volume to the analysis and interpretation of Paul Celan's cycle of poems *Atemkristall*, as if he were trying to enter into a discourse with the poet that Heidegger had failed to establish.

Galician

J Beswick, University of Southampton, Southampton, UK

© 2006 Elsevier Ltd. All rights reserved.

Language Classification

Galician is a Romance language derived from Vulgar Latin, belonging to the family of Ibero-Romance language varieties, and specifically, to the Galaico/Galician-Portuguese linguistic area. Termed *Galiza* by pro-Portuguese groups; in Galician, the language is *galego*.

Historical Overview

Galicia is the northwest region of Spain. One of three self-governing regions, the indigenous language of over 3 million people shares coofficial status with Castilian but linguistic origins with Portuguese, whose independence initiated diversification of Galician-Portuguese linguistic systems. By the 17th century, Galician varieties had lost prestige functions to Castilian, solely retained for oral intra-group purposes. However, by the 1980s a regional constitution and a written standard, the *Normas Ortográficas da Lingua Galega* (RAG & ILGA, 1995), were endorsed.

The long-standing diglossic situation with Castilian has led to lexical interference, although the phonological system also exhibits some structural borrowing: unlike Portuguese, *b* and *v* are homogeneous phonetically, there are no phonological nasal vowels or distinctive voiced sibilants, and the *ceta* [θ] is present.

Two major differences between Galician/Portuguese and Castilian:

(1) Lat. Ĕ > Port./Gal. terra
Cast. tierra
'land'
Lat. Ŏ > Port./Gal. porta
Cast. puerta
'door'

(2) Castilian monophthongization:
Port./Gal. madeira
Cast. madera
'wood'
Port./Gal. pouco
Cast. poco
'little'

Phonological System

The three dialectal zones based on derivations of Latin -ANUM by García de Diego (1909)

(3) eastern -ao
western -an
central -ano

may be maintained, but like the *seseo* pronunciation of *c*, the *gheada*, the (variable) voiceless continuant pronunciation of *g* in certain western dialects, confirms Zamora Vicente's (1953) two linguistic zone thesis; *galego iriense* (west) and *galego lucense* (east) (Fernández Rei, 1990):

(4) Gal. amigo > ami[h]o
'friend' > ami[x]o
> ami[x^h]o

However, the *Atlas Lingüístico de Galego* (ILGA, 1990, 1995, 1999) highlight the continued presence of more diverse dialectal variation. For example, whereas Portuguese acquired V̂ or retained V[m] of word-final VN sequences, and Castilian retains V[n], Galician generally adopts a V[ŋ] resolution, but the following can also occur:

(5) Lat. GERMANU > Port. irmão [ãw̃]
'brother' > Gal. irmao [aw]
(center, east)
> irmán [aŋ] (west)
> irmá [a] (northwest)
> Cast. hermano [an]

The *Normas* also require [ŋ] for intervocalic *nh*:

(6) Gal. unha
'one' (fem. sing.)

Controversy surrounding the phonemic status of [ŋ] is based upon its syllable position (Veiga Arias, 1976; González González and González González, 1994; Beswick, 1999).

See Table 1 for a more complete display of the Galician Phonological System.

Morphology

The tense range is similar to Portuguese: no compound tense forms, but a personal infinitive:

(7) comeran cando eu os chamei
'they had eaten when I called them'

(8) para faceres iso, precisas axuda
'in order to do that, you'll need help'

Verbal periphrases express aspectual, modal, or temporal meanings:

(9) o neno está a chorar/ o neno está chorando
'the boy is crying'

Table 1 Galician phonological system

Oral Vowels

	Tonic		*Non-final atonic*		*Final atonic*	
a	[a]	*cama* 'bed'	[a]	*palabra* 'word'	[a]	*casa* 'house'
e	[e]	*cera* 'wax'	[e]	*escrito* 'written'	[e]	*lume* 'light'
	[ɛ]	*letra* 'letter'				
i	[i]	*clima* 'climate'	[i]	*último* 'last'		
o	[o]	*son* 'sound'	[o]	*época* 'era, period'	[o]	*novo* 'new'
	[ɔ]	*forma* 'shape'				
u	[u]	*grupo* 'group'	[u]	*portugués* 'Portuguese'		

Diphthongs

Falling			*Rising*		
ai	[aj]	*pai* 'father'	ia	[ja]	*copia* 'copy'
au	[aw]	*auga* 'water'	ie	[iɛ]	*ciencia* 'science'
ei	[ej]	*maneira* 'manner'	io	[jo]	*milenio* 'millenium'
eu	[ew]	*meu* 'my'	iu	[ju]	*diurno* 'daily'
iu	[iw]	*partiu* 'he, she breaks'	ua	[wa]	*igual* 'same'
oi	[oj]	*biscoito* 'biscuit'	ue	[wɛ]	*frecuencia* 'frequency'
ou	[ow]	*doutor* 'doctor'	ui	[wi]	*lingüista* 'linguist'
ui	[uj]	*puiden* 'I was able to'	uo	[wo]	*residuo* 'residue'

Consonants

Orthographic symbol		
b intervocalically	[β]	*beber* 'to drink'
b elsewhere	[b]	
c + e, I	[θ] or [s]	*cedo* 'early'
c + a, o, u	[k]	*carta* 'letter'
ch	[tʃ]	*chiste* 'joke'
d intervocalically	[ð]	*dedo* 'finger'
d elsewhere	[d]	
f	[f]	*feo* 'ugly'
g	[g] or [h]	*garfo* 'fork'
gu + e, i	[g]	*guerra* 'war'
l	[l]	*lei* 'law'
ll	[ʎ] or [j]	*allo* 'garlic'
m	[m]	*mesa* 'table'
n	[n]	*nó* 'knot'
ñ	[ɲ]	*viño* 'wine'
nh	[ŋ]	*unha* 'one'
p	[p]	*persoa* 'person'
q	[k]	*quente* 'hot'
r intervocalically, word finally r elsewhere	[ɾ]	*ira* 'anger'; *ser* 'to be'
r elsewhere	[r]	*rede* 'net'; *tenro* 'tender'
rr	[r]	*carro* 'cart'
s	[s]	*sabor* 'taste'
t	[t]	*tema* 'theme'
v intervocalically	[β]	*vivir* 'to live'
v elsewhere	[b]	
x	[ʃ]	*xente* 'people'
z	[θ] or [s]	*zapato* 'shoe'

(10) teño traballado moito cando era xoven
'I used to work very hard when I was young'

(11) o can foi atropelado polo coche
'the dog was run over by the car'

Words in *-n* and polysyllabic words in *-l* are variable in the plural according to the linguistic zone:

(12) o can 'dog' > os cans (west/standard)
> os cas (center)
> os cais (east)

(13) o animal > os animás (sporadic)
'animal' > os animales (west/center: castilianism)
> os animais (east/standard)

The second person dative pronoun *che* is syntactically optional as a solidarity dative:

(14) dóecheme a perna
'my leg aches'

Object pronouns have a fixed order, as in Portuguese; contraction is common:

(15) déullelo
deu + *lles* + *o*
'he gave it to them'

Third person accusative pronoun allomorphs are phonologically conditioned by final phonemes of preceding words:

(16) o/a/os/as - default
comen o pan
'they eat the bread'
cómeno
'they eat it'

Here, *n* may be a positional allophone: velar word-finally before the article but morphologically connected to the pronoun, syllable-initial, and hence, alveolar.

(17) lo/la/los/las - following -r/-s, leading to their loss:

vou beber + a
vou bebela
'I am going to drink it'

(18) no/na/nos/nas - following a diphthong. A widespread innovative trait:

farei o xantar
'I will make dinner'
fareino
'I will make it'

The definite article comprises two allomorphs:

(19) o/a/os/as - default

(20) lo/la/los/las - following -r/-s:
todolos dias
todos + os
'everyday'

Article/preposition contractions are common:

(21) ós luns
a + os
'on Mondays'

(22) dunha amiga
de + unha
'of a friend'

Syntax

Pronoun order is similar to Portuguese. Simple declaratives and interrogatives:

(23) A miña irmá tróuxome unha flor
'My sister brought me a flower'

(24) Falaronlle da festa?
'Did they talk to him about the party?'

Negative, subordinate, complex interrogatives:

(25) A muller non che deu as notícias
'The woman didn't give you the news'

(26) Sabes canto me custou a casa
'You know how much the house cost me'

(27) ¿Quen lle deu o libro?
'Who gave him the book?'

Gambia: Language Situation

Editorial Team

Gambia is one of the smallest countries of Africa, with an area of around 11 300 sq km. It extends along the river Gambia from the Atlantic coast some 350 km inward and is, apart from the coastline, completely surrounded by Senegal. Gambia's population is about 1.5 million (2004 estimate). The majority of Gambian languages are Niger-Congo languages, belonging either to the Western Mande or the Atlantic group. Gambian Mande languages include Mandinka, Soninke (or Serehulle), and Jahanka (closely related to Mandinka and Western Maninka). Atlantic languages spoken in Gambia include Fula (or Pulaar), Wolof, Jola-Fogny, Serer, Balanta-Kentohe, and Mandjak. In addition, English, the official language, and the English-based Creole Aku are spoken, as well as languages of a number of immigrant communities, for example, Lebanese Arabic. Linguistically and culturally, the Gambia shares many traits with neighboring Senegal. Apart from the different official languages – English in the Gambia, French in Senegal, reflecting different colonial histories – most Gambian languages are also spoken in Senegal, and some have an even wider West African distribution.

The languages with the highest numbers of speakers in the Gambia are Mandinka (402 500 speakers), Fula (233 300), and Wolof (146 650). The principal languages of wider communication are, apart from English, Mandinka, mostly spoken in the rural areas, and Wolof, mainly spoken in the urban areas of the coast. Fula is spoken mainly in the interior, with the up-river towns of Basang and Basse being about one half Fula and the other half Mandinka. Most of the population of these areas is bilingual in Fula and Mandinka, which are considered rural languages of the interior, even though Mandinka is also spoken in most costal towns. Wolof carries a certain social prestige and is associated with urban sophistication. It is the main language of Banjul, the capital. The only rural Gambian Wolof live on the north of bank of the Gambia river, around Farafenni and Kauur. Except where Wolof is a lingua franca, it is not found south of the Gambia river. Jola is the fourth most widely spoken language in the Gambia, found mainly in Fogny. The Jola are almost invariably bilingual, also speaking Mandinka. Many urban Jola adapt to other cultures, especially Wolof and Mandinka, and cease to use their own language. There is some suggestion that with increasing urbanization, Jola may gradually disappear. Balanta and Manjak speakers, many of whom are recent immigrants from Guinea Bissau, constitute only a small percentage of the population, living mostly in Fogny. Aku is an English-based Creole originating from the community of freed slaves that settled in the capital Banjul in the early 19th century. Unlike other West African Creoles, such as Krio in Sierra Leone, Aku is not used as a lingua franca, but is spoken by a small, but economically important group of Aku speakers living mainly in Banjul.

The language of formal education is predominantly English, which is used at all levels of state education, and is also being introduced as a subject in Arabic-speaking madrassas. Mandinka, Wolof, and Fula are used to some extent in education, as well as in adult literacy programs, but often the unavailability of suitable teaching materials and textbooks is a problem. Literacy in Roman letters, as well as in Arabic script, which is often used for writing the three main Gambian languages Mandinka, Wolof, and Fula, is comparatively low (in 2002 estimate), with a significant difference between males (45%) and females (31%).

Game-Theoretical Semantics

J Hintikka and G Sandu, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

The leading ideas of game-theoretical semantics (GTS) can be seen by considering the truth condition of a sentence S of an interpreted first-order language. Now, S is true in an obvious pretheoretical sense iff there exist suitable witness individuals testifying to its truth. Thus, $(\exists x)F[x]$ is true iff there exists an individual b such that $F[b]$, $(\forall x)\ (\exists y)F[x,y]$ is true iff for each a there exists an individual b such that $F[a,b]$, and so on. As such examples show, one witness individual can depend on others. Hence, the existence of suitable witness individuals for S means the existence of a full array of Skolem functions for S, such as the function f in the sentence $(\exists f)\ (\forall x)\ F[x,f(x)]$, which is equivalent to $(\forall x)\ (\exists y)\ F[x,y]$. Such arrays of Skolem functions can be seen to codify a winning strategy in a simple game (semantical game) between a 'verifier' V and a 'falsifier' F. The game G(S) associated with S is played on some domain in which the nonlogical constants of S have been interpreted. G(S) begins with S, but at each move the sentence that the players are considering changes. When a move is made, V chooses disjuncts and values of existential quantifiers, whereas F chooses conjuncts and values of universal quantifiers, proceeding from outside in. For G(∼S) a game rule tells V and F to exchange roles and continue as for G(S). If a play of G(S) ends with a true negated or unnegated atomic sentence or identity, V wins and F loses; if it ends with a false one, vice versa. S is true iff there exists a winning strategy for V and false iff there exists one for F. GTS amounts to the systematic use of such truth conditions.

Game-theoretical ideas thus enter into GTS as highlighting the role of Skolem functions in logical theory. For this purpose, the whole generality of game theory is usually not needed. For instance, the only failure of perfect information that needs to be considered is a player's ignorance of earlier moves because only the individuals chosen at such moves can be arguments of Skolem functions.

So far, GTS for quantified sentences merely spells out our ordinary concept of truth. In traditional first-order languages, truth in the sense of GTS coincides with truth according to a Tarski-type definition (assuming the Axiom of Choice). But the GTS treatment can be extended and varied in several ways not available otherwise.

1. By allowing informational independence in the sense of game theory, we obtain a more expressive logic called independence-friendly (IF) logic (cf. Hintikka and Sandu, 1989). The greater expressive power is due to the semantic job of quantifiers as expressing dependence relations between actual variables by means of their formal dependence on one another. In the received first-order logic, only some patterns of such dependence could be formulated because the dependence-indicating scope relation is nested and hence incapable of expressing other dependence patterns. This defect is eliminated in IF logic. The role of Skolem functions in GTS is illustrated by the fact that each IF first-order sentence has a sigma-one-one second-order translation, namely, the sentence that asserts the existence of its Skolem functions. Conversely, each sigma-one-one sentence can be translated into the corresponding IF first-order language.

2. The independence of a quantifier (Q_2y) from another quantifier (Q_1x) within whose syntactical scope it occurs can be expressed by writing it (Q_2y/Q_1x). Often it is convenient to restrict this notation to quantifiers of the form $(\exists y/\forall x)$ and to assume that existential quantifiers are independent of one another, as are universal ones. (This simplification is used in this article.) As this slash notation suggests, the semantics of unextended first-order IF languages is not compositional. The limits of compositional methods in the semantics of IF logics have been investigated intensively (Hodges, 1997), and the impossibility of compositional semantics for IF logic normally interpreted has been shown (Cameron and Hodges, 2001; Sandu and Hintikka, 2001). The strength and naturalness of IF logic thus throws serious doubts on compositionality as a desideratum in semantic

Game-Theoretical Semantics

J Hintikka and G Sandu, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

The leading ideas of game-theoretical semantics (GTS) can be seen by considering the truth condition of a sentence S of an interpreted first-order language. Now, S is true in an obvious pretheoretical sense iff there exist suitable witness individuals testifying to its truth. Thus, $(\exists x)F[x]$ is true iff there exists an individual b such that $F[b]$, $(\forall x)\ (\exists y)F[x,y]$ is true iff for each a there exists an individual b such that $F[a,b]$, and so on. As such examples show, one witness individual can depend on others. Hence, the existence of suitable witness individuals for S means the existence of a full array of Skolem functions for S, such as the function f in the sentence $(\exists f)\ (\forall x)\ F[x,f(x)]$, which is equivalent to $(\forall x)\ (\exists y)\ F[x,y]$. Such arrays of Skolem functions can be seen to codify a winning strategy in a simple game (semantical game) between a 'verifier' V and a 'falsifier' F. The game G(S) associated with S is played on some domain in which the nonlogical constants of S have been interpreted. G(S) begins with S, but at each move the sentence that the players are considering changes. When a move is made, V chooses disjuncts and values of existential quantifiers, whereas F chooses conjuncts and values of universal quantifiers, proceeding from outside in. For G(∼S) a game rule tells V and F to exchange roles and continue as for G(S). If a play of G(S) ends with a true negated or unnegated atomic sentence or identity, V wins and F loses; if it ends with a false one, vice versa. S is true iff there exists a winning strategy for V and false iff there exists one for F. GTS amounts to the systematic use of such truth conditions.

Game-theoretical ideas thus enter into GTS as highlighting the role of Skolem functions in logical theory. For this purpose, the whole generality of game theory is usually not needed. For instance, the only failure of perfect information that needs to be considered is a player's ignorance of earlier moves because only the individuals chosen at such moves can be arguments of Skolem functions.

So far, GTS for quantified sentences merely spells out our ordinary concept of truth. In traditional first-order languages, truth in the sense of GTS coincides with truth according to a Tarski-type definition (assuming the Axiom of Choice). But the GTS treatment can be extended and varied in several ways not available otherwise.

1. By allowing informational independence in the sense of game theory, we obtain a more expressive logic called independence-friendly (IF) logic (cf. Hintikka and Sandu, 1989). The greater expressive power is due to the semantic job of quantifiers as expressing dependence relations between actual variables by means of their formal dependence on one another. In the received first-order logic, only some patterns of such dependence could be formulated because the dependence-indicating scope relation is nested and hence incapable of expressing other dependence patterns. This defect is eliminated in IF logic. The role of Skolem functions in GTS is illustrated by the fact that each IF first-order sentence has a sigma-one-one second-order translation, namely, the sentence that asserts the existence of its Skolem functions. Conversely, each sigma-one-one sentence can be translated into the corresponding IF first-order language.

2. The independence of a quantifier (Q_2y) from another quantifier (Q_1x) within whose syntactical scope it occurs can be expressed by writing it (Q_2y/Q_1x). Often it is convenient to restrict this notation to quantifiers of the form $(\exists y/\forall x)$ and to assume that existential quantifiers are independent of one another, as are universal ones. (This simplification is used in this article.) As this slash notation suggests, the semantics of unextended first-order IF languages is not compositional. The limits of compositional methods in the semantics of IF logics have been investigated intensively (Hodges, 1997), and the impossibility of compositional semantics for IF logic normally interpreted has been shown (Cameron and Hodges, 2001; Sandu and Hintikka, 2001). The strength and naturalness of IF logic thus throws serious doubts on compositionality as a desideratum in semantic

theorizing in general. In any case, many noncompositional languages can be treated semantically by means of GTS.

3. GTS can be extended to natural languages by allowing the substitution of names for entire quantifier phrases, as in Hintikka and Kulas (1983, 1985). Then the meaning of this phrase has to be taken into account by suitable additions to the output sentence. For instance, a game step (amounting to existential instantiation) might take the players from a singular sentence of the form

(1) X — some Y who Z — W

to a sentence of the form

(2) X — *b* — W, *b* is a Y and *b* Zs

Perhaps the greatest difference between natural language games and formal ones is that in the former the order of the application of game rules can be indicated by means other than scopes (labeled tree structures), for instance by the lexical items in question. This shows the limitations of the notion of scope, as argued in Hintikka (1997). At the very least, the two functions of scope (parentheses) have to be distinguished from one another as indicating the limits of binding (binding scope) and as indicating logical priority (priority scope). This distinction helps, among other things, to solve the problem of donkey sentences.

4. GTS can accommodate any concept, logical or nonlogical, whose meaning can be captured by a rule or rules in a semantical game. Cases in point are anaphoric pronouns, epistemic notions, genitives, *only*, and so on (cf. Hintikka and Sandu, 1991). For instance, the semantics of anaphoric pronouns can be captured by construing them, in effect, as existential quantifiers ranging over the individuals hitherto selected by V and F in a play of a semantical game. This extendability of GTS to nonlogical concepts throws into doubt the possibility of any sharp distinction between logical and nonlogical concepts.

By means of IF logic, several mathematical concepts can be expressed on the first-order level that could not be captured in ordinary first-order logic, including equicardinality, infinity, (topological) continuity, and König's lemma. In general, IF logic extends greatly the scope of what can be done in mathematics on the first-order level (cf. Hintikka, 1996).

5. The notion of informational independence plays an especially important role in epistemic logic, including the logic of questions and answers. Their logic depends essentially on the logical properties of the desideratum of a question. Such a desideratum is of the form $K_I S$ where K_I means *I know that*. It expresses the epistemic state that an answer to the question is calculated to bring about. The question ingredient is now of the form $(\exists x/K_I)$ for wh-questions and $(\vee/K_I)$ for propositional questions. All the most important notions related to questions and answers can be defined by means of the slash notation.

6. The law of the excluded middle amounts to the requirement of determinacy in semantical games and, hence, is not always satisfied. Determinacy fails, in fact, in IF logic, where the negation $\sim$ is used but not the contradictory $\neg$ negation. The latter can be introduced by a fiat, but within the GTS framework this can be done only when it occurs sentence-initially. When both negations are present, we obtain a logic whose algebraic structure is that of a Boolean algebra with an operator in Tarski's sense. In that logic, we can define generalizations of such notions as orthogonality and dimension.

7. The failure of *tertium non datur* shows that IF logic is closely related to intuitionistic logic. In a sense, IF logic is in fact more elementary than ordinary first-order logic. For instance, an application of the GTS truth definition to a sentence does not involve infinite closed totalities of individuals even when the domain is infinite. If such totalities are relied on, we can give truth conditions also for sentences in which $\neg$ occurs internally. The resulting logic is as strong as the entire second-order logic (with the standard interpretation), even though it is first-order logic in the sense that all quantifiers range over individuals.

In general, GTS shows that our concept of negation is irreducibly ambiguous between the strong (dual) negation $\sim$ and the contradictory negation $\neg$. This fact explains a number of features of the behavior of negation in natural language (cf. Hintikka, 2002a).

8. The simplest type of IF sentence that is not translatable into ordinary quantificational notation is of the following form, known as a Henkin quantifier sentence:

(3) $(\forall x)\,(\forall y)\,(\exists z/\forall y)\,(\exists u/\forall x)\mathrm{F}[x, y, z, u]$

The negation $\sim$S of an IF sentence S can be formed in the same way as in ordinary logic. For instance, the negation of (3) is (4)

(4) $(\exists x)\,(\exists y)\,(\forall z/\exists y)\,(\forall u/\exists x) \sim\mathrm{F}[x, y, z, u]$

The 'independence-free' meaning of (4) is brought out by its equivalence with (5)

(5) $(\exists f)\,(\exists g)\,(\exists x)\,(\exists y)\,(\forall z)\,(\forall u)$
$((z = f(x)\ \&\ u = g(y)) \supset \sim\mathrm{F}[x, y, z, u]$

9. IF logic is misnamed in that it allows for the representation of more dependencies (not just more independencies) than ordinary logic. A case in point is constituted by irreducibly mutually dependent variables. In order to express them, we have to generalize the notion of function and to take seriously the idea that a functional identity $y = f(x)$ expresses a dependence relation (cf. Hintikka, 2002b). This can be taken to mean that if such an identity fails to have a truth value for some x_o, $f(x_o)$ has to be taken to represent a probability distribution. Such distributions must then be able to be reified so as to act as argument values, too. With this understanding, the mutual dependence of x and y satisfying the condition F[x,y] can be expressed by

(6) $(\exists f)\ (\exists g)\ (\forall x)\ (\forall y)\ (x = f(y)\ \&\ y = g(x)\ \&\ \mathrm{F}[x,y])$

which is obviously equivalent to

(7) $(\forall x)\ (\forall y)\ (\exists z/\forall x)\ (\exists u/\forall y)\ (x = z\ \&\ y = u\ \&\ \mathrm{F}[x,y])$

10. The GTS approach can be varied in other ways, for instance, by restricting V's strategies to recursive or otherwise constructive ones as discussed in Hintikka (1996). In a different direction, a semantic game can be divided into subgames with specific rules for the transfer of information from one subgame to another one. Such subgames can be used for the interpretation of conditional sentences (cf. Hintikka and Sandu, 1991).

11. The notion of truth is put into a new light by IF logic. Tarski's well-known result shows that truth cannot be defined in an ordinary first-order language L for L itself, even when the syntax of L can be represented in L, for instance by means of Gödel numbering. The reason is that quantifiers ranging over numbers as numbers and quantifiers ranging over numbers as codifying numerical expressions must be informationally independent of one another. This requirement cannot be implemented in the received first-order logic. Because such independencies can be expressed in IF logic, a first-order IF language allows the formulation of a truth predicate for itself. Because Tarski's theorem is thus due to the expressive poverty of traditional logic (rather than its excessive deductive strength, as usually thought), definability problems are no obstacles to the explicit use of the notion of truth also in natural languages (cf. Hintikka, 1996; Sandu, 1998). Because much of the recent philosophical discussion of the notion of truth has in effect been prompted by Tarski's undefinability theorem, most of this discussion has to be reconsidered.

12. GTS, in the sense used here, is characterized by the definition of truth of S as the existence of a winning strategy for V in a semantical game G(S) associated with S. This meaning of GTS has to be distinguished from other uses of games and game theory in logic and linguistics, such as dialogical games (including questioning games), games of formal proof, games of communication, and so on. There are interesting connections between these different kinds of games. For instance, games of formal proof can be considered as mapping the different courses that a play of a semantical game can take. Again, the strategies of deductive games are closely related to the strategies of the corresponding questioning games when all answers are known *a priori* to be true (i.e., games of pure discovery).

13. Historically, GTS was inspired by Ludwig Wittgenstein's notion of language game. Philosophically, these two share the idea that language-world relations are constituted by certain rule-governed human activities. This implies that intentional relations are dispensable in semantics. In neither kind of game are the moves normally made by speech acts or other language acts. Both games are objective in that their theory depends only on their rules.

In sum, GTS is not merely one branch of formal semantics among others. It is an approach to all semantics, based on the possibility of considering the language-world links as being mediated by games in the abstract sense of the mathematical theory of games.

Introduction

Gamilaraay (Kamilaroi) is an Australian Aboriginal language that was traditionally spoken over a large area in the northwest of New South Wales, from the Great Diving Range, near Tamworth, north and west to the Darling and Barwon rivers. There was a range of dialect variation within this region, mostly marked by vocabulary differences, with all the local groups identified as *gamil* 'no' *-araay* 'having'. The sociolinguistic history of Gamilaraay is typical of many southeastern Australian languages.

The first recording of Gamilaraay is a short word list collected in 1832 by Major Thomas Mitchell (1839), and there is quite an amount of vocabulary material collected by local landowners in the late 19th century. The missionary William Ridley (Ridley, 1856, 1875) lived among the Gamilaraay in the 1850s and studied the language, collecting vocabulary and making simple primers and Bible translations. In 1903 the surveyor R. H. Mathews published grammatical notes and a short word list; however, the first professional recordings of the language date from 1930, when the anthropologist Norman Tindale took down words in phonetic notation and collected a short traditional narrative text (Austin and Tindale, 1986). By that time, local Aboriginal social and cultural transmission had been so disturbed by the impact of European settlement (*see* **Australia: Language Situation**) that the two old men Tindale interviewed had difficulty recalling the story. In 1955, S. A. Wurm carried out extensive fieldwork in eastern New South Wales and at Boggabilla interviewed Peter Lang, who seems to have been the last fluent native speaker of the language. He died the following year. Wurm's materials included field notes and a 13-minute tape recording. In 1972–1974, Austin interviewed a large number of semispeakers who could recall up to 200 lexical items and fixed phrases from their youth, though none could produce sentences in the language. Using all the existing modern and 19th-century materials, together with comparative data from neighboring languages, one can obtain a fair but incomplete idea of the language and its structure.

From the 1940s onward, Gamilaraay ceased to be used as the main means of communication, although knowledge of words and expressions (such as plant, animal, and food names) continues until today. Since the 1990s, there has been intense local interest in the language, and strong support for its documentation and reintroduction. Austin (1992) is a bilingual dictionary that has been widely distributed; a hypertext version created by Austin and Nathan (1995) was the first fully hypertext bilingual dictionary on the World Wide Web.

As a result of local initiatives and with support from the New South Wales government, Gamilaraay is currently undergoing a language revival and is being taught both in adult education and primary school classes. A range of materials are now available on the language and its neighbor Yuwaalaraay, including a reference dictionary (Giacon *et al*., 2001), language lessons (Giacon, 1999), and a wordbook with accompanying music CD.

Language Relationships

Gamilaraay is closely related to its immediate western neighbors, Yuwaalaraay and Yuwaaliyaay. The languages share about 70% common vocabulary with Gamilaraay, and a similar grammatical system. Fortunately, Corinne Williams was able to study with the

Introduction

Gamilaraay (Kamilaroi) is an Australian Aboriginal language that was traditionally spoken over a large area in the northwest of New South Wales, from the Great Diving Range, near Tamworth, north and west to the Darling and Barwon rivers. There was a range of dialect variation within this region, mostly marked by vocabulary differences, with all the local groups identified as *gamil* 'no' *-araay* 'having'. The sociolinguistic history of Gamilaraay is typical of many southeastern Australian languages.

The first recording of Gamilaraay is a short word list collected in 1832 by Major Thomas Mitchell (1839), and there is quite an amount of vocabulary material collected by local landowners in the late 19th century. The missionary William Ridley (Ridley, 1856, 1875) lived among the Gamilaraay in the 1850s and studied the language, collecting vocabulary and making simple primers and Bible translations. In 1903 the surveyor R. H. Mathews published grammatical notes and a short word list; however, the first professional recordings of the language date from 1930, when the anthropologist Norman Tindale took down words in phonetic notation and collected a short traditional narrative text (Austin and Tindale, 1986). By that time, local Aboriginal social and cultural transmission had been so disturbed by the impact of European settlement (*see* **Australia: Language Situation**) that the two old men Tindale interviewed had difficulty recalling the story. In 1955, S. A. Wurm carried out extensive fieldwork in eastern New South Wales and at Boggabilla interviewed Peter Lang, who seems to have been the last fluent native speaker of the language. He died the following year. Wurm's materials included field notes and a 13-minute tape recording. In 1972–1974, Austin interviewed a large number of semispeakers who could recall up to 200 lexical items and fixed phrases from their youth, though none could produce sentences in the language. Using all the existing modern and 19th-century materials, together with comparative data from neighboring languages, one can obtain a fair but incomplete idea of the language and its structure.

From the 1940s onward, Gamilaraay ceased to be used as the main means of communication, although knowledge of words and expressions (such as plant, animal, and food names) continues until today. Since the 1990s, there has been intense local interest in the language, and strong support for its documentation and reintroduction. Austin (1992) is a bilingual dictionary that has been widely distributed; a hypertext version created by Austin and Nathan (1995) was the first fully hypertext bilingual dictionary on the World Wide Web.

As a result of local initiatives and with support from the New South Wales government, Gamilaraay is currently undergoing a language revival and is being taught both in adult education and primary school classes. A range of materials are now available on the language and its neighbor Yuwaalaraay, including a reference dictionary (Giacon *et al*., 2001), language lessons (Giacon, 1999), and a wordbook with accompanying music CD.

Language Relationships

Gamilaraay is closely related to its immediate western neighbors, Yuwaalaraay and Yuwaaliyaay. The languages share about 70% common vocabulary with Gamilaraay, and a similar grammatical system. Fortunately, Corinne Williams was able to study with the

last two fluent speakers of these languages in 1975 and compiled a basic reference grammar and vocabulary list (Williams, 1980). There is also a large amount of tape-recorded material, collected in the 1970s by amateur linguist Janet Mathews (a relative of R. H. Mathews), that is being mined for other data.

These languages are quite clearly related to Wiradjuri (Wiradhuri), spoken over a large area of central New South Wales, and Ngiyampaa and Wayilwan, spoken along the Lachlan River (Donaldson, 1980; Austin *et al.*, 1980), and are members of a single linguistic subgroup (see Austin, 1997). This subgroup belongs to the widespread Pama-Nyungan family, which covers the southern two-thirds of Australia (*see* **Australia: Language Situation**).

Linguistic Characteristics

Phonology

The phonological system of Gamilaraay is typical of languages of eastern Australia, with contrastive stops at five points of articulation, a nasal for each stop position, a single lateral, a flap, a semiretroflex continuant, and two glides. Table 1 gives the relevant consonants in their practical orthographic form. There are just three vowels: high front *i*, high back *u*, and low *a*, with a phonemic length contrast found in all syllables of words.

The general structure of Gamilaraay roots is CV(C)CV(C). Every word must begin with a consonant and end in a vowel, or *n, l*, or *y*. Word-initially, only nonapical stops and nasals and the two glides are found. Word-medially, there are limited consonant clusters, primarily homorganic nasal plus stop, and apical nasal or lateral plus peripheral stop (*b* and *g*). Vowel clusters are not found. Words borrowed from English are generally restructured to meet these phonotactic constraints, e.g., *wajiin* 'white woman' (from 'white gin'), *ganjibal* 'policeman' (from 'constable'). Word stress is entirely predictable from the phonological shape of words: primary stress falls on long vowels or on the first syllable of a word that does not contain a long vowel. Secondary stress is on each even-numbered syllable to the left or right of the primary stress (except that final short syllables are not stressed). Examples are *gamilaraay* [gʌˌmilʌˈɽɑːy] 'Gamilaraay', *bandaar* [bʌnˈdɑːr] 'kangaroo', *thinawan* [ˈt̪inʌˌwʌn] 'emu'.

Table 1 Consonants

Lateral				*l*	
Flap				*rr*	
Continuant				*r*	
Glide	*w*		*y*		

Morphology

Gamilaraay, like other languages of the Pama-Nyungan group, is entirely suffixing in its morphology. There are two major word classes: nominals and verbs, with nominals showing a rich system of case marking and verbs marking tense/aspect/mood and dependent clause categories. Nominals can be subdivided into substantives (which cover both noun and adjective concepts in a language like English), pronouns, and demonstratives. Minor word classes include adverbs, particles, and interjections.

Nominals in Gamilaraay inflect for case, with the syntactic functions of intransitive subject (S), transitive subject (A), and transitive object (P) showing a split-ergative pattern of syncretism in the case forms determined by animacy:

- For the first and second person pronouns, S and A fall together as a single (unmarked) form with P different, making nominative-accusative case marking.
- For third person pronouns and all other nominals, S and P fall together as a single (unmarked) form with A different, making ergative-absolutive case marking.

In addition to the three main cases (*nominative* for S, *ergative* for A, *accusative* for P), there are also the following case forms:

- *dative* marking alienable possession, and direction toward a place
- *locative* coding location in a place
- *ablative* coding direction from a place, and cause

The actual forms of the cases are affected by the phonological shape of the root, e.g., whether it ends in a vowel or not and what kind of vowel or consonant is root-final.

Gamilaraay has a well-developed system of nominal word-building morphology that involves suffixation between the root and case inflection. Categories encoded in word-building morphology include number (plural), having (e.g., *bagaay-baraay* 'Boggabri' (literally 'creek-having')), lacking (e.g., *yuul-ngin* 'hungry' (literally 'food-lacking')).

Pronouns in Gamilaraay distinguish three persons and singular, dual, and plural number; in the first person nonsingular, there is no inclusive-exclusive contrast (unlike other Australian languages). Table 2

Table 2 Pronouns

	A/S	*P*	*Dative*	*Locative*
1sg	*ngaya*	*nganha*	*ngay*	*nganunda*
1dl	*ngali*	*ngalinya*	*ngalingu*	*ngalingunda*
1pl	*ngiyani*	*ngiyaninya*	*ngiyaningu*	*ngiyaningunda*
2sg	*nginda*	*nginunha*	*nginu*	*nginunda*
2dl	*ngindaali*	*ngindaalinya*	*ngindaalingu*	*ngindaalingunda*
2pl	*ngindaay*	*ngindaaynya*	*ngindaayngu*	*ngindaayngunda*

sets out the basic pronoun forms. There are also bound pronouns for second person reference only; these are reduced forms of the free pronouns and are suffixed to sentence initial negative and interrogative particles only. Examples are the following:

(1) *Yaama-nda* *ngalingu* *wuu-rri* *dhinggaa*
Q-2sg 1dl.dat give-fut meat
'Will you give us meat?'

(2) *Gariya-ndaali* *dhinggaa* *nhama* *dha-la*
not-2pl meat this eat-imper
'Don't you two eat this meat!'

Verbs morphologically distinguish between main verb and dependent verb inflections. Main verbs encode tense and mood categories, distinguishing future, nonfuture (covering past and present time reference), and imperative. Dependent verbs occur in hypotactically linked clauses and mark relative present tense (giving background information about the main clause event) and relative future tense (typically expressing purpose). The relative future is formally future plus dative case. There are four morphologically determined verb conjugations: conjugation 1 is primarily transitive, conjugation 2 is primarily intransitive, and conjugations 3 and 4 are much smaller and have mixed transitivity. There are monosyllabic verb roots that occur in all conjugations. Table 3 sets out the verb conjugation endings.

Verbs show productive word-building morphology, including affixes that indicate the temporal reference of an event within the tense frame of the inflected verb, e.g., *-ngayi-* indicates 'event in the morning', *-mayaa-* 'event in the evening', and aspectual, e.g., *-waaba-* 'completive', or directional meanings, e.g., *-uwi-* 'back'. There are also transitivizing and detransitivizing affixes, which shift conjugation and transitivity, e.g., *-ala-* 'reciprocal', *-ngiili-* 'reflexive'. There are also limited category-changing processes with only nominalization marked by addition of a conjugation marker to the verb, e.g., *giili-y* 'urine' being productive.

The minor categories of adverb, particle, and interjection show no morphological variation.

Syntax

Like other Australian languages (*see* **Jiwarli**), Gamilaraay has relatively free word order and shows all possible orders of Subject, Object, and Verb, although there is a preference for A P V order; (Williams, 1980: 93) said this is found in 65% of examples. It also allows nouns and adjectives to be separated in the clause, with case agreement indicating which elements are constituents. Williams (1980: 96) gave the Yuwaalaraay sentence showing this:

(3) *Buma-ay* *dhayin-du* *buyabuya* *dhayin*
hit-nonfut man-erg thin man
wamu-bidi-ju
fat-big-erg
'The fat man hit the thin man'

When the adjective precedes the noun, no case marker needs to be attached to the adjective. Similarly, possessors (in dative case) may precede or follow the alienable possessed noun.

Gamilaraay interclausal syntax is relatively simple compared with some other Australian languages. Dependent clauses occur hypotactically, located on the margins of main clauses, and distinguish only between relative future tense (purposive) or relative present tense (with adverbial or adnominal interpretations, depending on context). There are no cross-clausal coreference restrictions (such as switch reference or syntactic ergativity). Examples from Yuwaalaraay (Williams, 1980: 117–122) are shown in (4), (5), and (6).

(4) *Girr* *ngaya* *nhama* *baa-nhi*
affirm 1sgnom that jump-past
nhaadhiyaan-di, *nginda* *garra-ldaay*
log-ablat 2sgnom cut-relpres
'I jumped off the log that you cut'

(5) *Nginda* *ngaaluurr* *burrulaa* *bayama-ndaay,*
2sgnom fish many catch-relpres
ngay *bulaarr* *wuu-na*
1sgdat two give-imper
'If you catch many fish give me two'

(6) *Ngaya* *yana-y* *walaay-gu,*
1sgnom go-nonfut camp-dat
dhinggaa *dha-ligu*
meat eat-relfut
'I am going to camp to eat meat'

Particles in Gamilaraay have scope over the whole clause and encode such semantic concepts as polar question, as in (1); affirmation, as in (4); and negation. There are different particles for negative imperative, as in (2), and negative statement, as in (7).

Table 3 Verb conjugations

Gardiner, Alan, Sir (1879–1963)

J B Walmsley, Universität Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Alan Henderson Gardiner was born on March 29, 1879 in Eltham, England. After attending Charterhouse School, he spent a year in Paris before first studying classics and then Hebrew and Arabic at Oxford. He next worked in Berlin for 10 years on Erman and Grapow's *Wörterbuch der ägyptischen Sprache.* From 1912–1914, Gardiner worked at Manchester University and then took up the life of a gentleman scholar, not unlike Charles Darwin. He died in Oxford on December 19, 1963.

Gardiner's main work was done in Egyptian philology and general linguistics. He made contributions in the former to both the major areas of philology, hermeneutics and textual criticism. The questions Gardiner set himself to answer in the latter were: What is 'language'? How does speech work? These questions, he believed, could only be properly approached within a comprehensive theory of speech. Important concepts in this theory were 'sentence' (revealing an intelligible purpose), 'language' (a "universally possessed science" (Gardiner,

1932: 62), and 'speech' ("universally exerted activity" [*ibid.*]). 'Language' comprised a list of words, along with syntactic rules and intonation patterns. The basic unit of language was thus the word, and the sentence was the basic unit of speech.

Gardiner's aim was to analyze a single "act of speech" (Gardiner, 1932: vii, 6). He interpreted 'the act of speech' less abstractly than those who came after him, as "a particular transient occurrence involving definite individuals and tied down to a special time and place . . . " (Gardiner, 1932: 71). For his analysis, Gardiner isolated four factors: the speaker, the listener, the thing-spoken-about, and the words used. Of these, linguists had conventionally concentrated too much on the last, and within this, on statements: "'questions' and 'requests' used barely to be considered sentences at all" (Gardiner, 1932: 209). Gardiner further established as attributes of the 'utterance' sentence **quality,** sentence **function,** and sentence **form,** the latter comprising both 'locutional form' (the right words in the right order) and 'elocutional form' (intonation).

Gardiner stands in a line of development leading from Wegener and de Saussure to Austin, Searle, and beyond. Not content to confine his attention to the sentence, he broke new ground, but found few disciples. Although many of his seminal ideas anticipated elements of Speech Act theory, Harris's 'integrationist' linguistics, and Relevance Theory, he wrote in a context poorly equipped to assimilate his ideas. Avowedly mentalist at a time when Bloomfield's brand of linguistics appeared to be "gaining ever new ground in [North] America," Gardiner wrote, "I . . . cannot believe . . . that the method of introspection is completely defunct" (Gardiner, [1932]1951: 344).

Gardiner's is a persuasive example of philological work interacting with general linguistics to enrich both disciplines.

Born on January 12, 1866 in Les Brenets (near Neuchâtel), Louis Gauchat studied Romance philology in Bern and Zurich, and later in Paris and Rome. In 1890, he obtained his Ph.D. with a thesis on the Francoprovençal dialect of Dompierre. After a short period during which he was a school teacher, Gauchat was appointed Privatdozent first in Bern (1893–1897), and then in Zurich (1897–1902); in 1902 he became professor of Romance philology in Bern, from where he moved again to Zurich in 1907, where he stayed until the end of his career. In 1926–1928, he was Rector of the University of Zurich. He died on August 22, 1942 in Lenzerheide.

Gauchat represents the typically Swiss blend of the German Neogrammarian type of Romance linguistics with French linguistic geography, lexicography, and medieval philology. He was instrumental in transmitting this fruitful conjunction of two national traditions of research to later generations of Swiss Romanists (among others J. Jud, K. Jaberg, W. von Wartburg).

Gauchat was a specialist in the Gallo-Romance family, especially of its eastern branch, now called Francoprovençal. He laid the foundations of dialectological research in the Francoprovençal dialects spoken in Switzerland (the so-called *patois de la Suisse romande*) through the publication of phonetic

1932: 62), and 'speech' ("universally exerted activity" [*ibid.*]). 'Language' comprised a list of words, along with syntactic rules and intonation patterns. The basic unit of language was thus the word, and the sentence was the basic unit of speech.

Gardiner's aim was to analyze a single "act of speech" (Gardiner, 1932: vii, 6). He interpreted 'the act of speech' less abstractly than those who came after him, as "a particular transient occurrence involving definite individuals and tied down to a special time and place . . . " (Gardiner, 1932: 71). For his analysis, Gardiner isolated four factors: the speaker, the listener, the thing-spoken-about, and the words used. Of these, linguists had conventionally concentrated too much on the last, and within this, on statements: "'questions' and 'requests' used barely to be considered sentences at all" (Gardiner, 1932: 209). Gardiner further established as attributes of the 'utterance' sentence **quality,** sentence **function,** and sentence **form,** the latter comprising both 'locutional form' (the right words in the right order) and 'elocutional form' (intonation).

Gardiner stands in a line of development leading from Wegener and de Saussure to Austin, Searle, and beyond. Not content to confine his attention to the sentence, he broke new ground, but found few disciples. Although many of his seminal ideas anticipated elements of Speech Act theory, Harris's 'integrationist' linguistics, and Relevance Theory, he wrote in a context poorly equipped to assimilate his ideas. Avowedly mentalist at a time when Bloomfield's brand of linguistics appeared to be "gaining ever new ground in [North] America," Gardiner wrote, "I . . . cannot believe . . . that the method of introspection is completely defunct" (Gardiner, [1932]1951: 344).

Gardiner's is a persuasive example of philological work interacting with general linguistics to enrich both disciplines.

He was instrumental in transmitting this fruitful conjunction of two national traditions of research to later generations of Swiss Romanists (among others J. Jud, K. Jaberg, W. von Wartburg).

Gauchat was a specialist in the Gallo-Romance family, especially of its eastern branch, now called Francoprovençal. He laid the foundations of dialectological research in the Francoprovençal dialects spoken in Switzerland (the so-called *patois de la Suisse romande*) through the publication of phonetic

tables, a systematic bibliography, and the collection of lexicographical and ethnographical data. This led to the impressive *Glossaire des patois de la Suisse romande*, the publication of which still continues, and he also contributed to the diachronic study of these dialects. But Gauchat was also a theoretician, whose work anticipated variational studies and (historical) sociolinguistics. Whereas in his 1890 dissertation he had accepted the idea of well-established dialect boundaries, he later rejected this Neogrammarian principle (1903, 1905), and replaced it with a diasystemic view of *patois*, seen as the dynamic product of demographical, cultural, socioeconomical, and political variables, and developing through mutual contact and under the influence of standard languages (1905, 1906, 1908, 1909). Gauchat, whose dialectological work was characterized by an anthropological dimension (1910), was also interested in the function of language as a guide to sociocultural reality and as the symbolic expression of a world view (1914).

Peter Geach was born in London in 1916. His mother was the daughter of Polish emigrants, and at the time of Peter's birth, his father was a professor of philosophy at Lahore, India. In the first years of his life he stayed with his mother and grandparents, but at the age of 4 he was separated from them and made the ward of a guardian. When he was 8 years old, he was sent to Llandaff Cathedral School. Shortly afterward, his father returned to England and started teaching him logic and philosophy. He thus became familiar with Russell and Whitehead's *Principia Mathematica* in his school days, before he went to Oxford to read philosophy at Balliol. In 1938 he converted to Catholicism. Upon graduation in the same year, he won a Gladstone Research Studentship and went to St Deiniol's Library, Hawarden, to do further research on the philosophy of McTaggart, whom he had admired since his father introduced him to his work. While still in Oxford, Geach met Elizabeth Anscombe, a recent convert like himself. They married in 1941. The marriage lasted more than 60 years, until Elizabeth Anscombe died in 2003. They had seven children. During the 1940s the family lived in Cambridge, where they were friends with Wittgenstein, who supported Geach's attempts to acquire a teaching post. In 1951 Geach became Assistant Lecturer in Logic at Birmingham University. He remained there consecutively as a Lecturer, Senior Lecturer, and Reader in Logic until 1966, when he was appointed to the Chair of Logic at Leeds University. He retired in

Peter Geach was born in London in 1916. His mother was the daughter of Polish emigrants, and at the time of Peter's birth, his father was a professor of philosophy at Lahore, India. In the first years of his life he stayed with his mother and grandparents, but at the age of 4 he was separated from them and made the ward of a guardian. When he was 8 years old, he was sent to Llandaff Cathedral School. Shortly afterward, his father returned to England and started teaching him logic and philosophy. He thus became familiar with Russell and Whitehead's *Principia Mathematica* in his school days, before he went to Oxford to read philosophy at Balliol. In 1938 he converted to Catholicism. Upon graduation in the same year, he won a Gladstone Research Studentship and went to St Deiniol's Library, Hawarden, to do further research on the philosophy of McTaggart, whom he had admired since his father introduced him to his work. While still in Oxford, Geach met Elizabeth Anscombe, a recent convert like himself. They married in 1941. The marriage lasted more than 60 years, until Elizabeth Anscombe died in 2003. They had seven children. During the 1940s the family lived in Cambridge, where they were friends with Wittgenstein, who supported Geach's attempts to acquire a teaching post. In 1951 Geach became Assistant Lecturer in Logic at Birmingham University. He remained there consecutively as a Lecturer, Senior Lecturer, and Reader in Logic until 1966, when he was appointed to the Chair of Logic at Leeds University. He retired in

1981. In 1985 he was a visiting professor at the University of Warsaw.

Geach has written influentially on many topics in the history and philosophy of logic. He did much to show that the problems regarding the meaning of linguistic expressions that have exercised medieval logicians are the same as the problems addressed by modern ones. He also argued that several central elements of the pre-Fregean logical tradition, in particular the theory of the distribution of terms, are ill-conceived and unsound. Geach strongly opposed the dominant trend in British philosophy during the 1950s and 1960s known as 'ordinary language philosophy,' especially the then popular view that ordinary language has nothing to do with formal logic. His *Reference and generality* (1962) was meant as an extended proof to the contrary, containing as it does numerous applications of logical techniques to the analysis of English sentences. Geach's observations and theses in this area have greatly stimulated research in formal semantics. The most famous example of this is his discussion of the nature of reference involved in the sentence 'Any man who owns a donkey beats it' (1962: 117), which has engendered a widespread concern with so-called 'donkey sentences' and with the semantics of anaphoric pronouns in general.

Geach has also applied methods of logical analysis to the philosophy of mind (*Mental Acts*, 1957) and to the philosophy of religion (*God and the Soul*, 1969). In ethics (*The Virtues*, 1977), he has sought to revive an Aristotelian type of doctrine of the virtues.

Gəʿəz

S Weninger, Philipps-Universität, Marburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Gəʿəz (Gəʿəz, Classical Ethiopic, Old Ethiopic) is the classical language of Ethiopia. Gəʿəz belongs to the Northern branch of Ethio-Semitic, which is part of South Semitic, a subgroup of the Semitic languages. The earliest extant texts are inscriptions from the 3rd century found in Northern Ethiopia, especially in the city of Aksum. From this time, Gəʿəz maintained its exclusive status as a medium of formal communication, until the 19th century, when it gave way to Amharic. Within the Ethiopian Orthodox Church it still holds a position comparable to the status of Latin in Catholicism. Gəʿəz was also the liturgical language of the Jewish community of Ethiopia, the Betä ʾƎsraʾel.

Gəʿəz is written in a quasi-syllabic script, developed on the basis of the Sabaean alphabet. Each sign represents either a combination of a consonant and a vowel or a simple consonant, e.g., አቡነ፡ ዘበሰማያት፡, representing the sequence *ʾa-bu-nä zä-bä-sä-ma-ya-t*, pronounced *ʾabunä zäbäsämayat* (‘Our father who art in heaven’). In its classical form, Gəʿəz phonology comprises 26 consonants plus a set of four labialized velar obstruents and seven vowels. Noteworthy are sets of lateral, pharyngeal, and laryngeal obstruents as well as a set of ejectives. In the traditional pronunciation as practiced by learned Ethiopians, many consonantal distinctions are lost under the influence of modern Ethio-Semitic languages.

Gəʿəz has a rich morphology based on the common Semitic system of three or four consonantal roots and vocalic patterns, with prefixes and suffixes used both in derivation and inflection, as in *ṣäḥafä* ‘he wrote’, *ṣäḥafku* ‘I wrote’, *nṣḥf* ‘we shall write’, *ṣäḥafi* ‘scribe’, and *mäṣḥaf* ‘book’. Grammatical categories of the noun are gender (male/female), number (singular/plural), and case (nominative-genitive/accusative). The verb has five tense–aspect–mood (TAM) categories (perfect, imperfect, jussive, imperative, and converb). Other categories of the verb are person, number (singular/plural), and gender (male/female, also for second person!). The syntax is based on a rather loose verb-subject-object word order, and agreement is not strict.

The vocabulary of Gəʿəz is to a large degree common Semitic. However, loanwords from Cushitic languages, especially Central Cushitic languages, form a sizable part of the Gəʿəz lexicon. Contacts with the Church of Alexandria paved the way during late antiquity for many Greek and, during the Middle Ages, Arabic loanwords. On the one hand, Gəʿəz shares many typological features with the Asian Semitic languages, such as Arabic or Hebrew. On the other hand, it shows features known from the modern Ethio- Semitic languages, which belong to the Ethiopian language area, also shared by the Cushitic languages, with their subject-object-verb syntax. The converb, already present in Gəʿəz, is typical for this area.

Gelb, Ignace J. (1907–1985)

G Buccellati, University of California, Los Angeles, CA, USA

© 2006 Published by Elsevier Ltd.

Coming from a strong philological background, Gelb developed an ever greater interest in theory, which he felt would help him better understand the data. This was within the atmosphere of great intellectual ferment that characterized the University of Chicago in the formative period of Gelb’s intellectual career, i.e., from the 1940s to the 1960s (and that, linguistically, can be characterized as Bloomfieldian structuralism). Within the Oriental Institute itself, other great Assyriologists were developing analogous interests, in particular Thorkild Jacobsen and Erica Reiner. This developing interest in theory took him in two major directions: the social sciences and linguistics. As a result, he did seminal work in both areas within the field of Assyriology, pioneering especially the application of a coherent methodology to explain structural relationships within the data. Besides linguistics, he contributed immensely to the study of socioeconomic structures in ancient Syro-Mesopotamia. His philological control of the data remained unparalleled throughout his career, lending an even greater credibility to his efforts.

He was born October 14, 1907, in Tarnow, Poland. He left when he was 18 to study first in Florence, Italy, and then in Rome, where he studied Semitic philology, and became particularly close to Giorgio Levi della Vida; he concluded his studies with a doctorate (laurea) from the University of Rome in 1929. He then went to the Oriental Institute of the University of Chicago, where he remained for the rest of his life. As a traveling fellow and research Associate from

1929 to 1941, he did fieldwork at archaeological sites in the Near East and was appointed assistant professor in 1941. Naturalized as a U.S. citizen in 1939, he volunteered for and was drafted by the U.S. Army in 1943. He served most of the war in England, France, and Germany, working on military intelligence for the Office of Strategic Services. He finished his tour working at the Trials at Nuremberg. He became a Distinguished Service Professor in 1965, a position he held until his retirement in 1978. He served as editor in charge of *The Chicago Assyrian Dictionary* from 1947 to 1955; the dictionary project had started in 1921, and Gelb's years served as the transition from a two-decade gestation period to the actual beginning of the publication.

Within the field of linguistics, two major types of contribution can be distinguished. In one particular area, the history of writing, he produced works of general theory while otherwise concentrating on the application of theoretical principles to specific bodies of data. *A study of writing* (1952c) is the most complete presentation of his theoretical approach to a theme of linguistic import. Interestingly, the book introduced the term 'grammatology,' which was acknowledged in an obscure footnote by J. Derrida in his book *Of grammatology* (1976: 83 and 323) – however far this book in fact is from the spirit and the intent of Gelb's work, for, as one might expect, Gelb's grammatology is rooted in history rather than in philosophy. From a linguistic point of view, Gelb's main contribution was in providing a rigorous framework for an understanding of writing as a structural system, whatever its historical idiosyncrasies and whatever the language it aims to express. He also made an important contribution toward a clarification of the concept of graphemics as an area distinct from paleography. He gave a major empirical application of his principles in the volume on *Old Akkadian writing and grammar* (1952b), published the same year as *A study of writing*. In earlier years (i.e., before he had defined the basic presuppositions of method but was in fact already applying them to the data), he had published *Hittite hieroglyphic monuments* (1939), a landmark study of a body of texts written in a distinctive writing system.

In a similar vein, Gelb's second major area of interest was devoted to the application of linguistic principles to the grammar and the lexicon of the two oldest attested Semitic languages, Akkadian and Amorite. The closest he came to writing a comprehensive theoretical statement on the matter was his *Sequential reconstruction of Proto-Akkadian* (1969). 'Sequential' refers to the way in which elements of external inflection fall into slots whose sequence is controlled by rigorous rules. These rules are shown to apply not only synchronically but also across time, allowing him to project the archaic shape of morphological forms into a phase immediately preceding the oldest one as historically attested. What is significant in this approach from a theoretical point of view is that (a) the diachronic reconstruction is based essentially on the coherence of the system, which is projected (with plausible arguments) into the earlier phase of the language, and (b) the description of the segmental nature of inflection has considerable impact on the synchronic understanding as well. His other works on Akkadian deal not so much with theory but with the application of more rigorous linguistic criteria to data that had been treated until then in an *ad hoc*, philological manner. Besides his *Old Akkadian writing and grammar* (1952b), his 'Notes on Von Soden's grammar of Akkadian' (1955) are particularly notable in this respect.

Another major aspect of his contributions to linguistics is in the field of onomastics. His keen interest in the field was occasioned by the fact that personal names are the major sources for three languages with which he had become involved – Old Akkadian, Amorite, and Hurrian. After earlier major publications, especially *Nuzi personal names* (1943) and *Glossary of Old Akkadian* (1973), his towering work in this area was his 'Computer-aided analysis of Amorite' (1980), in which he applied fully the theoretical principles stated in his *Sequential reconstruction* (1969) and showed, *inter alia*, how his method was particularly suited for a digital analysis of the data (this being the first major publication in the discipline to apply electronic data processing to a vast corpus).

What Is Gender and Why Do Linguists Study It?

The term *gender* will be used in this article to refer to the social condition of being a woman or a man. *Gender* in this sense is distinguished from *sex*, meaning biological femaleness or maleness. Sex is potentially relevant for areas of linguistic inquiry where biological mechanisms are at issue (e.g., neurolinguistics), but in most research on language what is relevant is the *social* differentiation of men and women in particular communities. Generally speaking, gender-linked patterns of language-use arise not because men and women are naturally different, but because of the way that difference is made significant in the organization of social life and social relations. The forms and precise social significance of gender can vary considerably across cultures and through time.

Gender in its 'men and women' sense is also distinct from the use of the term in linguistics to denote a grammatical category (*see* **Gender, Grammatical**). The relationship between linguistic and social gender has been of interest to researchers who study the linguistic representation of men and women, but it will not be considered here. Rather I will concentrate on empirical research investigating patterns of language-use linked to the gender of the language-user. This kind of research may be done within a number of academic disciplines and paradigms, but here I will be mainly concerned with research that adopts a broadly sociolinguistic approach.

Why is gender an important concern in sociolinguistics? First, because the social fact of gender differentiation is consequential for processes of general interest to sociolinguists, such as language variation, change, and shift. Gender must therefore be considered in any satisfactory account of those linguistic processes. But the influence does not run in one direction only. Just as gender influences the workings of certain linguistic processes, so language-using is part of the process whereby gender is produced and reproduced as a salient feature of the social landscape. Language can be seen as one resource used by social actors to construct various kinds of masculinity and femininity, aligning themselves with some gender positions and differentiating themselves from others. The study of language and gender, then, aims to illuminate both linguistic and social processes. For many researchers its goals are also political: gender is seen from a feminist perspective not as a neutral *difference* but as a socially constructed *inequality*.

Theorizing Gender: From Difference to Diversity

Both expert and popular discussions of gender and language-use have traditionally revolved around the question of what differentiates women as a group from men as a group. It should be said immediately that virtually none of the putative differences are categorical: statements about men's and women's

What Is Gender and Why Do Linguists Study It?

The term *gender* will be used in this article to refer to the social condition of being a woman or a man. *Gender* in this sense is distinguished from *sex*, meaning biological femaleness or maleness. Sex is potentially relevant for areas of linguistic inquiry where biological mechanisms are at issue (e.g., neurolinguistics), but in most research on language what is relevant is the *social* differentiation of men and women in particular communities. Generally speaking, gender-linked patterns of language-use arise not because men and women are naturally different, but because of the way that difference is made significant in the organization of social life and social relations. The forms and precise social significance of gender can vary considerably across cultures and through time.

Gender in its 'men and women' sense is also distinct from the use of the term in linguistics to denote a grammatical category (*see* **Gender, Grammatical**). The relationship between linguistic and social gender has been of interest to researchers who study the linguistic representation of men and women, but it will not be considered here. Rather I will concentrate on empirical research investigating patterns of language-use linked to the gender of the language-user. This kind of research may be done within a number of academic disciplines and paradigms, but here I will be mainly concerned with research that adopts a broadly sociolinguistic approach.

Why is gender an important concern in sociolinguistics? First, because the social fact of gender differentiation is consequential for processes of general interest to sociolinguists, such as language variation, change, and shift. Gender must therefore be considered in any satisfactory account of those linguistic processes. But the influence does not run in one direction only. Just as gender influences the workings of certain linguistic processes, so language-using is part of the process whereby gender is produced and reproduced as a salient feature of the social landscape. Language can be seen as one resource used by social actors to construct various kinds of masculinity and femininity, aligning themselves with some gender positions and differentiating themselves from others. The study of language and gender, then, aims to illuminate both linguistic and social processes. For many researchers its goals are also political: gender is seen from a feminist perspective not as a neutral *difference* but as a socially constructed *inequality*.

Theorizing Gender: From Difference to Diversity

Both expert and popular discussions of gender and language-use have traditionally revolved around the question of what differentiates women as a group from men as a group. It should be said immediately that virtually none of the putative differences are categorical: statements about men's and women's

linguistic behavior are almost invariably probabilistic, asserting that the analysis of a particular data sample has shown a statistically significant tendency for women to use feature X more than men, or *vice versa*. Well-known generalizations of this form include "women use more tag questions than men," "women's speech is closer to the prestige standard than men's," and "women are more polite than men." In each of these cases, the generalization has been contested because the evidence is not clear-cut: different studies have yielded conflicting results, and even researchers who accept the generalization would acknowledge that exceptions to it exist.

It is not coincidental that all the claims just cited covertly treat men as the norm and women as the gender whose behavior requires explanation. Explanations have had a tendency to psychologize, treating women's linguistic behavior as an expression of the personality traits they are thought to develop as a consequence of their distinctive social roles. For instance, the "women are more standard" generalization has been explained as a consequence of women's "status-consciousness," a psychological disposition which has been related in turn to women's own alleged social insecurity (since their status depends on that of the male head of household) and/or their desire to secure social advantages for their children, among other things by providing them with models of 'correct' speech. Even in the 1970s there was dissatisfaction with accounts like these, which relied on stereotypical and increasingly outdated understandings of women's social position. But more radically, since the early 1990s, the idea of gender as a simple binary difference – however conceptualized – has been subjected to intense critical scrutiny.

A particular problem critics have pointed to in the binary framework is its tendency to flatten out the internal diversity that exists within each gender category: the differences *among* women, or men, may be as great as or greater than the differences between the two genders. People are after all never *just* men and women, but are always men and women of particular ages, classes, ethnic and geographical origins, occupations, social roles and statuses, and religious and political beliefs. The form gendered behavior takes is inflected by these other dimensions of identity and experience. Older and younger women, or working-class and middle-class women, may be as different from one another as they are from their male peers; each of these groups may define its femininity more by contrast with the femininity of some other group of women than in opposition to masculinity. That is still a question of gender, but it is not simply about differences between men and women.

With broader definitions in mind, many researchers today have rejected the old assumption that an inquiry into gendered linguistic behavior is essentially a search for large-scale generalizations about the language used by women and men. The traditional preoccupation with gender *differences* has increasingly given way to a concern with gender *diversity* – in other words, with the use of linguistic variability as a resource for producing a range of masculine and feminine styles in different communities or contexts. Researchers follow the injunction to 'look locally' at the form gender identities and relations take in specific communities, on the grounds that gender-linked patterns of language-use will emerge from the localized social practices in which women and men are engaged. How our understanding of language and gender has been changed by this move from difference to diversity, and from a global to a more localized perspective, will be explored in the following sections.

Language and Gender in the Variationist Paradigm

The 'variationist paradigm' in sociolinguistics uses quantitative methods to investigate linguistic variation and change. In its classic form, pioneered by William Labov (*see* **Labov, William (b. 1927)**) and others in the 1960s, variationist research focused on two issues particularly: the distribution of linguistic variables (in most cases, phonological ones) across major demographic categories in a speech community (e.g., social class, ethnicity, sex), and the motivations and mechanisms of linguistic change. These issues are interrelated, since linguistic change does not usually involve a sudden break, but rather a gradual shift in the balance between already-existing variant realizations of a particular variable. The motivation for change is typically related to the social meaning of the variants involved, which is linked in turn to their demographic distribution.

Early in his career Labov studied the variable (r) – that is, the pronunciation or non-pronunciation of /r/ after vowels, as in *car, farm* – in the English of New York City. New York was historically non-rhotic (not /r/-pronouncing), but Labov found evidence that the incidence of rhoticity was rising. This change reflected speakers' desire to avoid the stigma attached to non-rhotic pronunciations, used most frequently by lower-class speakers as part of a generally low-status New York urban dialect. Women were more advanced than men in the shift. In an earlier study conducted on the island of Martha's Vineyard off the coast of Massachusetts, Labov had found that a centralized pronunciation of the diphthongs (ay) – as in

white – and (aw) – as in *out* – was gaining ground from the non-centralized pronunciation. Centralized diphthongs were associated with local island tradition rather than with external measures of status (e.g., wealth, power, education); the motivation for adopting them was a desire to assert a 'real islander' identity in opposition to the incomers and tourists who increasingly dominated the island economy. This change was led by men.

These findings, and analogous ones from other speech communities, suggested that women and men were instrumental in different kinds of changes. Women led in "change from above" (the adoption of prestige pronunciations for variables whose social meaning people are consciously aware of, like (r) in New York City), and men in "change from below" (the adoption of particular non-prestige pronunciations as an expression of identity, which takes place below the level of conscious awareness, as with (ay) and (aw) on Martha's Vineyard).

The idea that men and women play different roles in language change was not new. Eighteenth-century enthusiasts for 'fixing' language, who saw change as undesirable, frequently attributed innovations to women's fickleness; but later commentators who saw language change as 'natural' or progressive more often held some variant of the view cited by Otto Jespersen (1922): "Women do nothing more than keep to the traditional language which they have learnt from their parents and hand on to their children, while innovations are due to the initiative of men."

The advent of variationist studies, which offered solid statistical evidence for the involvement of both genders in change, should arguably have put an end to the myth of female conservatism, but in fact that myth seems to have influenced the way at least some early variationists interpreted their findings. Two senses of conservative were sometimes confusingly conflated: the sense in which it means "resistant to any change," and the political sense in which it connotes allegiance to the values of a dominant class. The women who were leading the shift towards /r/-pronouncing in New York City were clearly being innovative rather than conservative in the first sense; but the fact that women typically led in changes towards a prestige norm was often taken to evidence conservatism in the second sense – women's alleged status-consciousness made them susceptible to the influence of middle-class prescriptions for 'correct' usage. Meanwhile, 'real' innovation occurred in local vernacular speech by way of change from below, which was then thought to be initiated most often by men. Probably the most familiar of all variationist claims about gender – that the speech of women in all classes tends to be closer than men's to the prestige standard – avoids the issue of conservatism/innovation, and is to that extent less confusing, but essentially it makes the same point and reflects the same understanding of femininity and masculinity.

It should be noted, however, that this familiar claim no longer accurately represents the orthodox variationist position. In 1990, after reviewing the accumulated evidence, Labov formulated some general principles that can be summarized as follows:

- Where sociolinguistic variables are stable, men use higher frequencies of nonstandard variants than women.
- Where there is change from above, women lead in the adoption of the incoming prestige variant.
- Where there is change from below, women are more advanced than men in their use of the innovative variant.

The big change here is that women are now considered prototypical leaders in *both* the major types of linguistic change. There is, then, no overall tendency for women to favor more standard and men more vernacular pronunciations, or for women to be (socially or linguistically) conservative. The neat gender-complementarity of the older model has broken down, producing what Labov dubs a "gender paradox": women "conform more closely than men to sociolinguistic norms that are overtly prescribed, but conform less than men when they are not' (Labov, 2001: 293). And this paradox is not amenable to explanations in terms of women's distinctive social roles or psychological dispositions, since a major part of what now needs to be explained is, precisely, the non-uniform behavior of women as a group.

At this point it becomes relevant to return to the theoretical development mentioned above, namely the shift from gender *difference* to gender *diversity*. In a diversity framework it is not assumed that all women's or all men's linguistic behavior will be uniform. If we accept that women and men are internally diverse groups, the fact that some women do one thing while others do the opposite need not be considered a paradox at all.

In research conducted in the1970s in coastal South Carolina, Patricia Nichols (1998) observed younger black island women shifting more markedly than men of the same generations from the Creole variety Gullah towards Standard English (SE). Older black women on the other hand were more conservative than their male peers. Nichols's account relates the women's behavior to local labor market conditions. Historically, islanders had lived by farming, but economic change had propelled them into waged labor on the mainland. Their opportunities, however, were

circumscribed by gender. Whereas black men could find well-paid jobs in construction, the best-paid positions available to black women were mainly clerical, demanding standard language and literacy skills. Hence black families had increasingly invested in educating girls, with the result that younger women made more use of SE than either men or older women who had not had the same economic opportunities. White mainland women (who did not speak Gullah but rather Appalachian English) were a different case again: where their husbands, more advantaged in the labor market than either women or black men, earned enough to support dependents, they did not have the same need as black women to work outside the home and had neither opportunity nor incentive to adopt a more standard speech.

This study provides an early illustration of the benefits of 'looking locally.' Nichols showed that people's linguistic behavior was not simply a consequence of their membership of particular social categories – the fact that they were men or women, black or white – but rather emerged from their attempts to negotiate local arrangements involving those categories (e.g., a labor market segregated by gender and race). Looking locally suggests that conflicting tendencies in women's sociolinguistic behavior may reflect the different choices, opportunities, and risks that different groups of women are faced with. Even if it is found (as in some studies it has been) that the *same* women's behavior instantiates both elements of Labov's paradox (each in relation to a different set of linguistic variables), we may be able to explain this conflict by looking carefully at the social conditions these women inhabit.

Why, though, is it specifically women whose behavior exhibits the paradox? Merely invoking the diversity of women cannot provide an answer, since men are no less diverse. If Labov's principles have any validity or value, do they not point to some global, or at least supra-local, phenomenon requiring an explanation?

Penelope Eckert is among those variationist researchers who believe that looking locally can and should be combined with 'thinking globally' about gender. Making use of the concept of the community of practice (CoP), a group defined by the engagement of its members in some joint endeavor (examples might include a workplace team or sports team, a church congregation or a teenage gang), Eckert points out that language-using is shaped by the activities and practices in which it is embedded; and that in most societies, gender exerts an influence on the activities people habitually engage in. If men and women differ in the range of CoPs they belong to and/or the terms on which they participate in joint endeavors, those differences can be expected to have linguistic consequences – and perhaps not only local ones, though since CoPs are local entities, investigation must begin at the local level.

Eckert carried out research in a suburban high school near Detroit, where identity and social practice were organized around the contrast between 'jocks' (who embrace the official definition of school success, e.g., participating actively in both academic and extra-curricular pursuits) and 'burnouts' (who reject the school's values and resist active participation in its official culture). Affiliation to these groups was marked linguistically as well as in other ways: several phonological variables that are currently undergoing a change known as the Northern Cities Vowel Shift were appropriated differentially to signify either jock or burnout identity. In both groups, however, young women were more advanced than young men in their use of the variants that marked group membership: linguistically, women were the 'jockiest' jocks and the most 'burned-out' burnouts. So although the jock and burnout women were less similar to one another in terms of actual linguistic behavior than any other pair of subgroups in Eckert's sample, at a more abstract level they had something in common – a tendency to be extreme in their linguistic marking of group membership.

Eckert's account of this tendency could be seen as a reworking of the old idea about women's status-consciousness – except that status is reinterpreted in terms of participants' local values. She suggests that women use language to claim status as 'good' jocks or 'good' burnouts, and gives reasons why this strategy is especially favored by women. The reasons have to do with the different terms on which women and men participate in the jock and burnout CoPs. Men can gain status by displaying ability (e.g., in sports or fighting), but even if women possess the same skills, they are not rewarded in the same way. A woman's status has more to do with her appearance and personal style: her capital as a jock or a burnout is, in other words, largely symbolic. Consequently, women work harder to assert in-group status through symbolic details like the styling of their jeans and the pronunciation of their vowels. Eckert has suggested that this pattern is not confined to adolescent subcultures. Women, as the subordinate gender, may perceive their status and legitimacy to be in question in all kinds of CoPs; making a symbolic display of in-group credentials – pointedly presenting oneself as, say, a 'real' lawyer/athlete/truck driver, using resources such as language that are accessible to women as well as men – is one way to deal with this marginal social positioning. If so, it is evident that inequality, rather than just difference, shapes the relationship of language to gender; and there are

patterns of gender inequality which are not just operative at local level.

These observations may bear on Labov's gender paradox: the combination of conformist and non-conformist behavior identified with women in his principles could be produced by women asserting their status in both global terms (by adopting variants that carry supra-local prestige) and local settings (by adopting variants that can be used to assert one's credentials as a member of a particular community). If both kinds of status are relevant to an individual, as will commonly be the case in societies where people have some range of identities and roles, then there is no contradiction in seeking to maximize both; and as Eckert points out, there are reasons why women might be particularly active in this regard.

Eckert has described her approach as part of a third wave in variationist studies. In the first wave, researchers used survey techniques to reveal large-scale patterns of variation and change: Labov's research in New York City is an example. A second wave employed ethnographic methods to study the workings of variation and change in particular local communities, relating linguistic variables to the social categories and divisions that were meaningful for community-members themselves. The third wave is similar to the second in that research is ethnographic and locally-based, but the focus of interest shifts from simply correlating linguistic and demographic variables to investigating the social meaning of linguistic variables and their clustering into styles. It is these styles rather than individual variables that are linked to membership of local social categories (for instance, jock and burnout). Eckert comments: "Since [the third wave] takes social meaning as primary, it examines not just variables that are of prior interest to linguists (e.g., changes in progress) but any linguistic material that serves a social/stylistic purpose. And in shifting the focus from dialects to styles, it shifts the focus from speaker categories to the construction of personae." These preoccupations give the new wave of variationist research a good deal in common with another major current of language and gender research, which is the subject of the next section.

Gendered Discourse Styles

Variationist investigations of gendered linguistic behavior were motivated in the first instance by a desire to understand the workings of variation and change as general linguistic processes. Other researchers, however, were motivated to investigate gendered linguistic behavior primarily by an interest in what language might contribute to the social processes whereby gender is reproduced. These researchers often sought to identify what I am calling 'gendered discourse styles,' in other words, ways of speaking that signal masculinity or (more commonly) femininity by deploying characteristic combinations of linguistic features. Whereas variationists took the link between gender and particular realizations of phonological variables to be arbitrary in linguistic terms, researchers of discourse style often supposed that the linguistic markers of men's style and women's style would be functionally linked to the traits and roles of men and women.

One early attempt to delineate a gendered discourse style in English (though on the basis of the analyst's own intuitions rather than empirical investigation) was Robin Lakoff's account of women's language (WL), first proposed in 1973. The characteristic features of WL included a preference for milder over more strongly tabooed expletives, exaggerated politeness, an elaborate color vocabulary, use of empty adjectives ('lovely,' 'divine') and intensifiers ('*so* nice'), hedging to reduce the force of an utterance and/or the speaker's degree of commitment to it, and phrasing statements as questions, using rising intonation and/or end-of-sentence question tags. This formally, rather ill-assorted cluster of features is made coherent by attending to their functions in discourse. Many of them, Lakoff argued, communicate insecurity: a lack of confidence in one's own opinion, a desire to avoid giving offence and a need to seek approval from others. Lakoff saw these as traits women were socialized to develop in order to conform to mainstream notions of femininity, and she linked this insecurity to women's subordinate status. WL, from her perspective, was a display of women's culturally-imposed powerlessness in a male-dominated and sexist society.

This line of argument places Lakoff among the many 1970s feminists who adopted what has been called the 'dominance' approach to language and gender – in other words, they sought to explain gendered linguistic behavior in terms of men's power and women's subordination. But since Lakoff clearly regarded WL as inferior, for many purposes, to the alternative (which she labeled 'neutral language' rather than 'men's language' – Lakoff understood femininity to be not parallel to masculinity but marked with respect to it), her work has frequently been cited as an example of the 'deficit' approach, in which women's behavior is judged negatively against an explicitly or implicitly male norm. (In my own view Lakoff's work has elements of both deficit and dominance, and if anything, the dominance view is stronger.)

In the 1980s both the abovementioned approaches were challenged by the advent of a '[cultural] difference' approach to the question of gendered discourse styles. Difference researchers (the best-known of whom is the interactional sociolinguist Deborah Tannen – *see* **Tannen, Deborah (b. 1945)**) argued that women and men, like members of different ethnic or national groups, behaved differently because they had unconsciously internalized contrasting norms for the performance of communicative acts. These norms, in turn could be related to the gender-differentiated organization of children's peer groups, which both reflected and reproduced quasi-cultural differences in men's and women's general orientation to the world. Proponents of this argument have frequently suggested, for instance, that women typically orient to people and relationships while men are more oriented to objects and information. Such a difference in orientation might be expected to affect many aspects of discourse performance: what topics men and women prefer to talk about, how they address others, how they manage the floor, how much and what kind of politeness they use, the frequency of questions and minimal responses, the form of directives, the use of deixis, even the structure of nominals referring to objects.

Research along the lines suggested by the difference approach continues. One notable development is the use of corpus methods to search for statistical evidence of the predicted gender-linked patterns in multi-million word collections of texts. The computing scientist Shlomo Argamon and his associates, for instance, have recently developed an algorithm for which they claim 80% success in deciding whether a formal written text was composed by a man or a woman. The criteria used, which were originally selected using purely statistical methods, include the frequency of determiners and quantifiers (high frequency is a good predictor of male authorship) and that of personal pronouns, especially *I, you, she* and their variants (high frequencies are associated with female authorship). The researchers suggest that these correlations arise because of men's greater concern with specifying the properties of objects and women's greater concern to specify relations between persons addressed or mentioned in the text. A simplified version of their algorithm, known as the Gender Genie, has been made available on a website, inviting visitors to measure their own or others' writing against the Genie's templates for male and female style.

But this quest for gendered discourse styles, whether couched in terms of deficit, dominance, or difference, is vulnerable to the same criticism as early variationist work: that it is a global approach, predicated on a binary model of gender, and taking insufficient account of intra-gender diversity. Many researchers on gender and discourse have taken Penelope Eckert's point that new understandings of gender not only require us to look locally (the community of practice framework is influential in discourse studies, too), more radically they "shift the focus from speaker categories to the construction of personae."

In discourse studies as in third wave variationist research, the emphasis is now on mapping the way social actors use what Eckert calls "linguistic material that serves a social/stylistic purpose" (which in this current of work may be anything from a single vowel segment to an entire code) to construct gendered personae. Some researchers are influenced by Judith Butler's notion of gender as 'performative,' that is, not given in advance but brought into being when people act (or in this case, speak) in ways that are culturally coded as masculine or feminine. It follows that social actors may construct a range of gendered personae (not just one each), and that their performances may include unusual, artificial, or deviant ones. There has been considerable interest recently in researching the linguistic performance of gender by non-mainstream sexual subjects in a variety of cultures and contexts – gay men, lesbians, transgendered individuals, sex workers, drag artists, and teenage nerds who remain marginal to peer-cultures organized around heterosexual activity. In more mainstream cases, too, the diversity of gendered performances and personae is emphasized, with many studies setting out to show that particular CoPs perform gender linguistically in particular ways, and that even a single small group of women, or men, will often make use of stylistic resources to shift between different kinds of femininity or masculinity.

Conclusion

This article has focused on the nature, results, and implications of the recent shift from difference to diversity as a framework for studying the relationship of language and gender. It should be noted that this shift, though unquestionably important, is not by any means total. Third wave variationist research coexists with older approaches in which the mechanisms of variation and change and their relationship to demographic categories continue to be explored. The quest for general accounts of men's and women's discourse styles continues to flourish alongside studies that 'look locally.'

But to the extent that language and gender researchers' approaches have shifted, the resulting research is now beginning to prompt its own questions, and in some cases criticisms. Perhaps the most significant of

these is whether the new emphasis on looking locally, stressing the diversity of gendered behavior, is resulting in a reluctance to 'think globally' about gender. For some commentators, this caution about treating gender as an overarching social category risks losing sight of the political dimension of language and gender research. It may also distort the overall picture by over-emphasizing the agency of subjects in constructing gendered personae, while downplaying the structural and institutional factors that in reality constrain their performances. The anthropologist Susan Phillips, for instance, has observed that the way gender is enacted locally by the members of an adolescent peer-group or the inhabitants of a village is not unaffected by what happens above the local level, in state and other public institutions (and in contemporary conditions, one might add, in transnational institutions like global communications media). The challenge, then, is to articulate the analysis of local and diverse social practices with an analysis of larger social and political structures.

Gender and Language

M Talbot, Centre for Research in Media and Cultural Studies, Sunderland, UK

© 2006 Elsevier Ltd. All rights reserved.

The field of language and gender is multidisciplinary in scope. Practitioners can be found not only in linguistics and gender studies but right across the humanities and social sciences, including in anthropology, cultural studies, education, literary studies, social psychology, and sociology. The point of contact is feminist interest in language and, in that sense, there is always some form of political agenda and engagement. After thirty years, the accumulated research is now wide-ranging. Explicitly feminist in focus are explorations of gender positioning, in representations in media broadcasting and print, and in interaction in the media and other institutions. To give an indication of the range of coverage, a few examples are: examinations of the dynamics of classrooms privileging boys (e.g., Swann, 1992); case studies of women in public life (e.g., Walsh, 2001); the wisdom and efficacy, or otherwise, of institutional guidelines on non-sexist language use (Cameron, 1998a); sexism in press coverage, e.g., victim-blaming in rape reporting (Clark, 1998), and the reinforcement of normative gender positions in reporting on a sexual harassment conviction (Talbot, 1997); the rhetoric of physically abusive husbands and the disenfranchisement of their wives (Adams *et al.,* 1995). Less explicitly feminist, but nevertheless coming from a feminist standpoint are studies of the minutiae of conversational interaction between close friends in same-sex groups (e.g., Coates, 1996), a study of bilingual youth culture (Pujolar, 2000), and many and varied storytelling analyses: of accounts of pregnancy (Freed, 1996), socialization of children at family dinnertables (e.g., Ochs and Taylor, 1992), lesbian coming-out stories (Wood, 1999), among many others. *The handbook of language and gender* is a detailed overview of the field, providing a full and indicative representation of its diversity and depth (Holmes and Meyerhoff, 2003).

Since the early 1990s, two prominent issues in language and gender have been: a sustained critique of 'gender differences' as the research agenda and a need for firmer theoretical grounding. The sections that follow address both of them in turn.

Querying the 'Gender Differences' Agenda

There is a well-known claim that men and women use interactional styles associated with power and solidarity, respectively (*see* **Power and Pragmatics**). The existence of distinct female and male interactional styles has now gained widespread acceptance, to the extent that they have entered popular 'common sense' (cf., e.g., Talbot, 2003). There is a considerable weight of evidence to support this view, including research on politeness (e.g., Holmes, 1995) and on physical alignment and eye contact in conversations (e.g., Tannen, 1990). In a detailed study of compliments and compliment responses, for example, Janet Holmes has found New Zealand women using compliments a great deal more than men do, with compliments between women being used to consolidate solidarity between the giver of the compliment and the recipient. Holmes found that men, on the other hand, tend to find compliments threatening and may use mock insults and sparring to cement friendships instead. The overall picture is one of polarization; of men's talk as power based and competitive, women's talk as solidarity-based and cooperative.

According to the 'difference' framework, gendered language patterns are a consequence of distinct female and male subcultures. In this view, women and men behave differently because they are segregated in childhood. Boys, who tend to play in large groups with hierarchical social structure, learn to value status and become power-focused; whereas girls, who tend to play in small groups of 'best friends,' learn to value intimacy and become solidarity-focused. In the process, children acquire different gender-appropriate behavior. They enter adult heterosexual relationships with differing expectations about friendly interaction and consequently encounter problems of miscommunication (e.g., Tannen, 1991). These miscommunication problems have been presented as analogous to cross-cultural miscommunication.

There are many detailed critiques of the 'difference' framework (e.g., Cameron, 1995; Crawford, 1995; Freed, 1992; Talbot, 1998; Troemel-Ploetz, 1991; Uchida, 1992). The foremost concerns are the erasure of power and a tendency to overgeneralize, brought about by disregard for contextual considerations other than gender. Sex segregration in childhood is greatly exaggerated (Thorne, 1993). Claims about miscommunication among adults disregard issues of conflict over rights and obligations in times of social change (Cameron, 1998b). 'Gender differences'-based research on language depends on untenable dichotomies; critics have argued for far more nuanced understandings of power and solidarity, and indeed gender, and query the continued usefulness of the whole line of inquiry. The question: 'how does the language of women and men differ?' is no longer

considered an appropriate starting point for research into gendered patterns of behavior seeking to further a feminist understanding of patriarchal social relations and sexual inequality. It is a question that assumes its answer lies with, precisely, differences. In short, the search for 'gender differences' has become an impoverished framework that flattens out the enormous range, variation, and richness of interaction between women and men, boys and girls.

Beyond 'Difference': The Poststructuralist Turn

In an article reflecting on the history of the field, Barrie Thorne points to a skewed emphasis on the micropolitics of face-to-face interaction – at the expense of the social structures and processes in which all face-to-face interaction is embedded – and accounts for it in terms of a 'strategy of deliberate one-sidedness' advocated by Erving Goffman (1983) (*see* **Goffman, Erving (1922–1982)**). This analytic move generated a rich body of work on gender in everyday interaction but also, Thorne argues, generated a rift between theory and analysis (Thorne, 2001). Since the early 1990s, attempts to resolve this rift have drawn on critical theory, particularly poststructuralist theories of discourse and identity (*see* **Poststructuralism and Deconstruction**). A conceptualization of identity as flux is notable in recent research, strongly influenced by poststructuralism and paralleling developments in related fields (e.g., *see* **Critical Discourse Analysis**).

A poststructuralist position on discourse and identity provides an alternative to the polarized conceptualization of gender identity. While the 'gender difference' approach operates with a static conception of distinct male and female identities, developed and fixed in childhood, in a poststructuralist account identity is much more fluid. Feminist criticism from this perspective takes language as the site of the cultural production of gender (e.g., Weedon, 1997). In this view, gender identities are not pre-given, but constructed in discourse; individuals take up positions in their enactments of discourse practices. This view serves to caution against making *a priori* assumptions about gender identity, such as by implicitly setting up a masculine-feminine dichotomy as the starting point (by determining to look for 'differences' in the behavior of women and men). It also serves as a corrective to assumptions of homogeneity in the social identities and relationships of women and men. Research influenced by poststructuralism examines not gender difference but the construction of gender identities. This approach to language and gender is grounded in the assumption that subjectivity is constituted in discourse. In discourse, individuals are positioned as social subjects who are gendered in specific ways.

Careful avoidance of bipolar categories of gender, and the comparative approach that goes with them, is a characteristic of recent research. Some analysts are explicit in their grounding in feminist theory (e.g., contributors to Hall and Bucholtz, 1995; Bucholtz *et al.*, 1999) and directly or indirectly interrogate categories such as masculine, feminine, heterosexual, white, middle-class, etc. 'Exceptional speakers' (the title of Kira Hall's contribution to the *Handbook of language and gender*) are increasingly studied on their own terms, rather than as exceptions to an over-rigid model that is unable to accommodate them. Such cases of 'footnote deviance' (Holmes and Meyerhoff, 2003: 354) include the 'tomboys' and 'sissies' that a 'two-cultures' account cannot accommodate adequately, and the African-American women whose verbal behavior awkwardly refuses to fit the pattern for a 'feminine' interactional style based on middle-class white Americans. This attention to liminal users of language has produced new areas of interest within the field of language and gender, e.g., an emerging field centering on 'the sexual and gender deviance of previous generations' (ibid.), which its practitioners have given the name 'queer linguistics' (*see* **Queer Talk**). A related point is that there are parallels between developments in the study of gender and of ethnicity, where the converse is taking place. A shift in focus to gendered subjectivity has generated increasing attention to masculinities. Just as whiteness is receiving critical attention, rather than occupying an invisible position as the 'non-ethnic' norm, so masculinities are being examined as constructed identities. Language and gender has seen significant expansion to encompass sexual orientation, ethnicity, and multilingualism, and, to some extent, class, involving analyses of spoken, written, and signed gendered identities (*see* **Intercultural Pragmatics and Communication; Multilingualism: Pragmatic Aspects**).

Gender and Political Discourse

L Martín Rojo, Universidad Autonoma de Madrid, Madrid, Spain

© 2006 Elsevier Ltd. All rights reserved.

Little research has been done on the topic of gender and political discourse, although this issue may show us the extent to which a gendered division of power holds worldwide. (The recent work done by Walsh 2001 is noteworthy in this field.) While highly revealing of the key role that language and other styles of communication play in the political arena, investigations of gender and politics also shows how social closure occurs, hindering access and skewing the representation of certain genders, classes, and social groups in this area.

This article will deal primarily with issues of institutional politics, particularly parliamentary, legislative, and government politics, and not with issues of everyday politics. The very lack of women in government and parliaments explains in part the lack of research done on gender and political discourse

(in Peterson and Sisson Runyan, 1993, conclusive figures from all continents around the world can be found. Also see Wodak, 2003). In fact, most countries that acknowledge the objective of promoting equality between women and men do not have parity governments, and only in a very few exceptional cases do women even comprise 40% of parliament. The fact that women's social position is not as strong as men's, despite progress made in certain areas of the world, has been linked to masculinist hegemony, which in turn is connected to social class and ethnic differences in different ways in different places. Masculinist hegemony is diffuse since, as Walsh (2001: 17) indicates "it is embedded in impersonal discursive practices and institutional structures that are historically associated with men." Indeed, when statistics are broken down by gender in the areas of education, health, economic participation, or wages, women as a group are still at a disadvantage. The fact that women's social position remains weak, although to varying degrees in different countries around the world, explains why women encounter resistance and difficulties in joining the political sphere and other prestigious areas of society such as business or academia. In the legitimization of this social weakness, several factors seem to play a significant role, like religion (Balaghi, 1994), culture (Graumann-Ubale, 1996), or historical reasons (Dudink, 2004).

Because our societies perceive a process of evolution and modernization leading women's presence to increase daily throughout the world, their greater presence in the Western sphere, considered to be more 'evolved' ('civilized'), is considered a given. Nevertheless, these assumptions are not always justified and mask some important aspects of the issue. For instance, while the female participation rate in northern European countries stands out as an exception (Gomard, 2001), other countries considered to be less Western or civilized, such as Costa Rica and Rwanda, apply the quota system.

Seemingly, only where strong women's movements conjugate certain political clout with the defence of women's social position and interests can political change increase women's numbers in politics. Thus, the political earthquake hitting Rwanda or Northern Ireland has uniquely placed women's movements actively participating in the peace negotiations and making noteworthy contributions to national reconciliation. These women have subsequently stood for public office in elections in order to change policies. Analogously, the processes of political decentralization in Spain and recently also in the United Kingdom, have enabled the conditioning of women politicians in regional parliaments and governments, and in regional governments (thereby enabling the recent constitution of a parity national government in Spain with women who have demonstrable experience in government).

Such examples seem to indicate that barriers encountered by women are so frequent and substantial that the process is sometimes not gradual (as it seems to have been in Scandinavia). At times, the political rules are modified, opening the way for women only after deep change altering the political equilibrium, or even only after strong social upheavals. But the figures are overwhelming and leave little room for optimism. The results of deep changes in the political rules, if they do suffice, are not always positive. Developments in the so-called Eastern European countries illustrate how political change can lead to lower female participation (Hungry, Poland, Rumania, and Russia are clear examples. See Peterson and Sisson Runyan, 1993: 54ff.; see also Matland, 2003). Seemingly therefore, only where strong women's movements conjugate certain political clout with the defense of women's social position and interests can political change increase women's numbers in politics.

This article reveals how language barriers (i.e., difficulty in attaining an education and socialization generating an acceptable communicative style for intervening in the social arena), and cultural barriers (i.e., difficulty in fully participating in traditionally male-oriented fraternal networks within political organizations), are rooted, but also reinforce structural barriers (particularly, the unequal distribution of women and men in the public sphere of politics; differences in women's socialization that do not prepare them to overcome cultural and linguistic barriers, etc.).

In order to show these links, the first section of this article analyses the issue of gendered communicative styles, the difficulties they present for women, and what women contribute by modifying traditional patterns. Section two demonstrates how perceptions of gendered communicative styles affect the way women involved in politics are represented and evaluated. Finally, section three examines the role played by the current discursive order in reproducing gender inequality and how language barriers are linked to other cultural and structural barriers.

The Discursive Order: Is There a Feminine Style in the Political Arena?

Several of the authors who have worked on this issue have used 'communities of practice' as their starting point to suggest that the political domain constitutes a discursive order characterized by certain ways of speaking and evaluations about their appropriacy

that are traditionally associated with males. That is, professional politicians are seen as an "aggregate of people who, united by a common enterprise, develop and share ways of doing things, ways of talking, beliefs, and values, -in short practices" (Eckert and McConnell-Ginet, 1999: 186). The fact that this community of practice has traditionally been made up of males explains why such ways of speaking and values have taken shape as dominant and why everything departing from this practice and these values is appraised as unsuitable or unacceptable. While no specific communicational style is demanded of men in the political arena, women do not seem to have an appropriate one available. This inequality in demands leads to a process of exclusion, making it difficult for women to gain access to important resources and positions in the organization. This situation is an example of social closure (social domination).

This exclusion may, in turn, give rise to a situation in which access to these high-level resources and positions is achieved by means of adaptation to the dominant styles and forms. Within research on language and gender, certain linguistic choices have been identified as masculine in style: being more assertive in one's expression and exercising of power (which includes highlighting rather than concealing responsibility for decisions or actions), and being direct and confrontational with adversaries in political debates. These traits, which are not necessarily found among all males, appear most clearly in two specific spheres in the political arena: in parliamentary debates and in the creation and maintaining of fraternal or peer networks, both within political organizations (parties and unions), and in informal interaction between members of the same or of different parties. Ties are made and negotiations take place outside a formal context through these networks, making them as important in politics as they are in other areas.

These masculine stereotyped forms are increasingly rejected by women. Thus, within the British Labour Party, for instance, Harriet Harman has criticized what she terms the "militaristic" and "macho" language of the laddish coterie who surround Blair, claiming that talk of "big guns," "big hitters," and "big beasts" is not how women refer to one another (the Guardian, 9 March 1999; also see Walsh's analyses, 2001: 100ff.). However, these discursive practices are highly effective in building fraternal networks in political parties.

Researchers have also attempted to define the traits characterizing a feminine style. Authors such as Blankenship and Robson (1995), using a study of a corpus of political discourse in the United States between 1990 and 1994, have identified the following five traits: basing political judgments on concrete, lived experience; valuing inclusivity and relational nature of being; conceptualizing the power of public office as a capacity 'to get things done' and to empower others; approaching policy formation holistically; moving women's issues to the forefront of the public arena.

At least the first three of these five traits have been considered paradigmatic examples of how women tend to tackle communication in other public spaces, such as business. However, as with all characterizations of feminine styles, we can never be sure whether these styles actually appear in women's discourse or whether they are rather a perception or a representation of women in social positions of responsibility, based on and shaped by gender stereotypes (Martín Rojo and Gómez Esteban, 2002, 2004).

Lastly, we cannot overlook the different ways in which women devoted to politics act. In fact, Walsh (2001: 11) identified three models explaining these differences. First is the accommodation model, required by a male-oriented cultural context, in which women adapt to dominant practices both in their management of conflict and in their expression of authority. Nevertheless, adapting to molds and forms traditionally considered typical of male politicians often leads women politicians to be seen as strange specimens, behaving as would be expected of a leader, but not of a woman (Margaret Thatcher is a paradigmatic example). The fact that women to whom this categorization is attributed are seen as exceptions does not contribute to promoting the feminization of the political sphere.

The second model is what Walsh terms the critical difference model, which could be characterized as the search for cooperation instead of adopting an aggressive, confrontational style. Here, there is a risk of being perceived as weak and ineffectual, or to put it bluntly, as poor professionals having arrived where they are thanks to the paternalism of males who have given them an undeserved place due to quota policies (this phenomenon could be seen as similar to what occurs in leadership positions in the sphere of labor, cited by authors such as Holmes, 1995; Tannen, 1996; Martín Rojo and Gómez Esteban, 2002, 2004). As indicated by Deborah Cameron (1992: 76), regardless of how this style is judged, adopting it contributes to rectifying the traditional dichotomy between private and public spheres and the unequal distribution of women and men in these spheres. It could be expected, however, that with the gradual feminizing of the public sphere, adopting this style would contribute to transforming the rules and values that govern it.

The third model is what Walsh calls the performative model and consists of women switching between

the other two models depending on the communicative situation and other factors. Although this model is perhaps the most widely followed (see Romaniuk, 2004 for similar conclusions), it remains invisible. As stated in Fairclough's (1989: 182ff.) analysis, although Margaret Thatcher herself used a hybrid style, carefully conjugating selected features associated with middle-class femininity and 'authoritative expressive elements' used by men politicians, the masculine model was insistently attributed to her (she was described as 'the best man in the cabinet'). Her model was even resorted to in order to masculinize and discredit the work of other women (Walsh cites the case of Margaret Beckett when competing for Labour leadership in 1994 (Walsh, 2001: 72–73).

This frequent alternating of styles does not depend so much on a rational choice made by these women but is rather a reflection of the tension they experience, leading them to use different options. Examples such as the new President of the Parliament of Andalusia, who declared her will to exercise her power "not to follow in the footsteps of men, but to open new paths on which womens' footsteps may be seen . . ." are still few and far between. In addition, as Wodak (2003) points out, female MPs in EU parliament display a wide range of identity constructions, and gender can be overridden through national and ideological affiliation.

Furthermore, while serving as an avenue for women to develop their own style of leadership, stressing the differences between the masculine and feminine forms of exercising power also involves risks. Emphasizing some aspects of what has been defined as specifically feminine leadership, or defending its virtues, may in fact serve only to further stereotype and marginalize women in leadership and politics. It is also paradoxical that this marginalization comes at a time when certain cracks can already be seen in the towering edifice of the two-sex and two-gender system. (Given that people are now more aware of the fact that gender differences are socially constructed, distinctions between the genders have weakened and a host of different ways to be a women or a man are expressed more freely.) (Freed, 2003). And what is even more highly suspicious is the vulgarized version of the positive view of differences in academic circles that is so prevalently found in the media, the self-help industry, and books on popular psychology. *Cosmopolitan* has made en effort to tie these different ways of speaking with the presence of certain hormones or the different constitution of our brains. Through dichotomies and oversimplification, these media relentlessly stress that women and men shop, think, speak and behave differently.

Beyond any doubt, in the current discursive order of politics, we find that the requirements are somewhat flexible and open for men (if male politicians adopt a nonconfrontational style, this behavior would not be necessarily interpreted as a sign of weakness), but restrictive for women who are also harshly criticized and often excluded from a sphere where dominant practices have been imposed throughout history. We therefore find ourselves up against an example of domination and exclusion that is reproduced and bolstered by discursive practices. From this perspective, at least three areas stand out for their importance: parliamentary debate, government tasks, and peer relations in nonformal contexts. The first area is linked to the adversarial style, the second to how power is expressed and managed, and the third to building one's own identity and one's own group identity.

As indicated by other authors (Puwar, 1997; Sreberny-Mohamadi and Ross, 1996; Walsh, 2001), women find a confrontational style, ranging beyond parliamentary debate, to be alienating and inhibiting. As Sedgemore (1995: 54) indicated, in parliament, when differences are small, they must be magnified and when they do not exist at all, they must be fabricated.

However, cultural differences can be observed in how this confrontation is managed. In the British parliament, for instance, both the parliamentary procedure and the physical layout itself stimulate confrontation (Sedgemore, 1995: 54). Legal interventions are allowed in debate where one speaker gives way to another so that he or she can make remarks that tie in with the line of argument. These legal interventions are not permitted in other parliaments. But illegal interventions, highly effective in increasing the aggressive tone of the debate, are found in all parliaments. When made on a group basis, these interventions consist of interjections, stomping, noise, and all types of comments demonstrating support or disapproval of the speaker, while on an individual basis, illegal interventions usually consist of comments such as 'that's a lie' or 'resign.' In this light, Shaw's figures (2000) illustrate that legal or illegal interruptions in parliamentary debates are often made by men. By not availing themselves of these interventions, women therefore limit their access to the floor and thus relinquish their power in the debates.

In the second area, government tasks, the way is gradually being paved for new styles of leadership incorporating more cooperative and less assertive traits that afford greater scope for interpersonal relationships. Yet these innovations come up against

resistance even when advocated by men. (As compared with his predecessor's brusque, pushy, severe style, Spanish prime minister Rodríguez Zapatero has been dubbed 'Bambi' by the opposition for his conciliatory style). This resistance is even greater when it comes to women, since their practices, based on an ideology that understands power as a resource to transform society and not to dominate others, are not considered to be chosen rationally but rather considered to be a sign of inherent weakness. In her campaign within the British Labour party, Beckett's reluctance, for instance, to speculate on potential situations in which she would push the nuclear button were not understood as a political position in itself, i.e., the rejection of a populist discourse on security, or support for nuclear disarmament. Instead, they were understood as a sign of weakness invalidating her as a candidate.

Lastly, in the third area, peer relations, the role played by practices traditionally associated with masculine forms is interesting to observe. Especially interesting is the role they play in informal contexts (coffee breaks, mealtimes, parties, Christmas dinners, nights out), where relationships become less formal, power relationships are less manifest, and more stable networks emerge. Organizations and political parities are built on these types of relationships. Paradoxically, obstacles are also presented for women in participating in this type of situation, especially in highly masculinized sectors. It is important to draw attention to the social implications of this marginalization of women in male peer networks, since at the higher levels of organizations real power resides in these groups. Because networks like these are the basis for choosing the candidates called upon to represent the people in elections, these relationships play a key role in either promoting or thwarting women's inclusion.

Reducing political relationships to 'gentlemen's clubs,' 'big guns,' or 'political babes' excludes those who explore new, more democratic types of political systems. Therefore, analyzing the barriers to women in politics better enables us to show the potential results of women's equalitarian participation in politics that could, in turn, open up the possibility of new ideological positions. It has, for instance, been noted that women's role in peace negotiations after various conflicts in Northern Ireland, Rwanda, or Israel-Palestine has opened up forms of reconciliation that are not based on excluding any of the parties. Also, the awareness of being in a position of weakness in politics can lead to a less assertive style and the seeking of consensus in decision-making and exercising power. Moreover, women's involvement in grassroots movements is bringing about new brands of politics that are closer to people's everyday life experience and needs. This less elitist style, more adapted to voters' specific situations, means that politics becomes much more democratic. Romaniuk (2004) also shows the emergence of a new communication ideology that values private forms of communication in the public sphere. It has also been indicated that women are less susceptible to corruption (according to Johon Mathiason, former Director of the UN Division for the Advancement of Women), perhaps because of their exclusion from the fraternal networks where so many things are negotiated outside the regulatory sphere of the political arena. Lastly, women's role in changing the political agenda seems noticeable, although it is done from NGOs, since in certain countries, consensus has been reached between women of different political parties to address issues such as abuse of women, or to respond to some of the claims of the women's movement's.

The Social Representation of Female Politicians

What we have seen thus far shows how the style adopted by women in positions of power in government or parliament is sometimes not as important as how these styles are perceived and represented. Several authors have studied how representations reproduce gender stereotypes and traditional dichotomies separating the public and private spheres.

The media play an important role in reproducing and disseminating dominant representations of women involved in politics (Ross and Sreby-Mohammadi, 1997). One of the main reasons, in addition to the deep rooting of traditional visions indicated by Walsh, is that most of those who own or control the media are men who assume that the ideal reader will also be male.

Due to the strong impact of gender inequalities in the distribution of social spaces, women's presence in the public sphere is still viewed as exceptional. Thus, as Fowler (1991) indicated, male presence undoubtedly overshadows female presence in the British press, which reaffirms women's underrepresentation in the public sphere (King, 1992: 133), feeding the lack of female models. The few articles which are devoted to women reproduce traditional stereotypes, that is, these articles include references to women's family ties (husbands, fathers, children, etc.) or provide information on their marital status, thereby reaffirming their image as dependent (on the will or actions of others). These articles often also include observations and value judgments regarding their physical aspect (for instance in the campaign for Labour

Party leadership "where Blair was a youthful 40-something, Beckett was post-menopausal" (*Daily Express*, 24 June 1994). Adjectives used to describe women usually place the emphasis on their physical and emotional qualities and nearly never on their professional or moral worth. And when the adjectives do evaluate their moral worth, they usually refer to traditionally imposed traits (fidelity, resignation, care for others) or traditionally disdained traits (domineering, masculine in style, wielding of 'female weapons'). (Mcdonald, 1995: 50, points to double moral standards in social spaces.)

Therefore, when women's action as high-level politicians is represented in the media, we find they are considered tokens, that is, as symbols of their gender rather than as individuals. For example, when a minister is criticized for her actions, her entire gender's suitability for government is called into question, while a man's incompetence only calls into question his own incapacity and never that of his entire gender.

Thus, as Kanter points out, when women are seen as token they are subject to three perceptual tendencies: greater visibility, contrast or comparison, and assimilation (1977: 130ff.). Greater visibility, contrast, and comparison can be observed in the scrutinizing and criticism of women's action in government. Walsh (2001) has studied how women's actions within the Labour Party, the Blair government ('Blair's babes'), and the Welsh and Scottish parliaments are continuously compared and benchmarked against male ways of speaking and values. Women in government are the marked gender (Tannen, 1996). As a result, their behavior is observed and judged for its suitability. If their performance is judged to be negative, then the whole gender is discredited. Suffice it to cite how Welsh Agriculture Secretary Christine Gwyther was treated in the media for being vegetarian.

This discredit leads on to the third tendency – assimilation. Women in the public sphere are seen as more masculine than in the domestic sphere. Thus, those women who do not convey an empty image of power are perceived as macho. This is not a positive representation, however, since they are seen not as women, but as rejected specimens. They are the iron ladies, the women who wear the trousers, pseudo-men (for research on virilization and exclusion suffered by these women in the public sphere see Martín Rojo and Gómez Estaban, 2002).

The observation of these perceptual tendencies leads us to reason that the women who do not take part in this dichotomized distribution of public and private spheres are the ones who pose the greatest contradictions and tensions in the media. Page's analysis (2003) of the representation of leading barrister and wife of the current British prime minister Cherie Booth Blair in the British press shows these contradictions. The stereotypically passive representation of Cherie Blair might be seen as securing her husband's political status against the potentially destabilizing influence of her representation as a powerful professional in the public domain, thereby reinforcing gendered norms (Page, 2003: 570). What has yet to be studied is the impact of her representation as a professional on other working women. Here, Page's analysis seems to show that while her professional worth is not questioned, she is considered to be an exception.

Barriers Constituting a Glass Ceiling and Potential Action

Language barriers hamper women's access to politics both on an institutional and an everyday level in both parties and organizations. We must not overlook female illiteracy rates, higher than those of men throughout the world. While women have not yet been socialized to compete in the political arena, what is relevant is how in the current order of discourse the dominant practices and values deprive them of the tools they need to make a way for themselves.

We have already seen the dilemmas faced by women in politics as well as the dominant social representations in the media. While no specific communicational style is demanded of men in institutional politics (except some stylistic preferences for expressing conflict and opposition in debates and for exercising power), women politicians do not seem to have an appropriate style available to them. This inequality in requirements gives rise to a situation where both maintaining their traditional features and assuming traditional masculine traits leave women looking out of place in politics. As a result, men's prevalent position in organizations is not threatened, but rather effectively reproduced and therefore bolstered.

In addition, while stressing the differences between the masculine and feminine forms of exercising power provides an avenue for women to develop their own style of leadership, it also conceals other restrictions they face at entry and the thwarting of new ideological positions and ways of doing politics.

Changing this situation requires changing discourse's social order so that it is open to other types of participation. Carbó (2003) studies one outstanding example of the changes required, the Zapatist commander Esther's intervention in the Mexican

Parliament, the first by a nonparliamentarian, indigenous woman. Yet, we know that the order of discourse cannot be modified unless other orders are. In fact, it is no coincidence that women have attained socialization in less competitive areas, like politics in regional parliaments and local institutions, because less power is wielded there (i.e., the autonomous governments in Spain and the United Kingdom) or in situations where overcoming crises has required innovative solutions.

Language barriers are inextricably tied to other barriers, particularly cultural ones, favoring particular practices and ways of doing politics. This link explains why women MPs in Britain were not even able to change the evening sessions in the British Parliament to make their work and home lives compatible. Their attempt was seen as a break with tradition, and the same holds true for their rejection of the dominant aggressive, masculine style.

Both cultural and language barriers invariably lead us to structural barriers, to the unequal distribution of social spheres, and to the relegating of women outside the most prized public sphere. Social changes are threatening this order but have not yet changed it. More deeply rooted and seemingly more difficult to change is the strong link traditionally established between power and masculinity. Gender stereotypes are still shaping role stereotypes in the political arena. As a result of the association of power and masculinity, when women reach high positions, they can be regarded as deviant examples or virilized women (Golda Meyer and Margaret Thatcher are outstanding examples). This association between genders and roles promotes essentialist discourses attributing specific worth and possibilities. As a result, we see that the political arena is a gendered social space.

As long as women's numbers in politics are low, it will be difficult to see that the problems we face as women (abuse, less research on diseases affecting women, lower salaries, difficulties in attending to both work and children, etc.) are problems of society as a whole. In democracy, justice must be for the entire population. Women's greater presence in politics would help to bring these issues to the fore and would encourage solutions attenuating social exclusion and injustice.

Gender, Grammatical

G G Corbett, University of Surrey, Surrey, UK

© 2006 Elsevier Ltd. All rights reserved.

Gender is a feature of special interest because it provides a dramatic demonstration of just how different languages can be. For many of the Indo-European languages it is an important feature that is realized in a high proportion of utterances. In most Daghestanian languages, such as Tsakhur, it is still more salient: it suffuses the syntax and morphology, appearing on some unlikely agreement targets. In almost all the languages of the Austronesian family, it is simply missing. This article first examines the definitions of gender to ensure that we are comparing like with like. There has been careful research to do this, and it will become clear that within the languages that do have gender there is a considerable variety of possible gender systems. This is particularly apparent in the ways in which speakers assign nouns to genders. Gender systems may have sex as a component, as in languages with masculine and feminine genders; but, equally, sex may be irrelevant, as in the Algonquian languages, where the distinction is between animate and inanimate. This article outlines the distribution of gender in the world's languages, and finally considers prospects for investigating the feature further.

Terms

The word 'gender' derives from Latin *genus* via Old French *gendre,* originally meaning 'kind' or 'sort'. There are many kinds of noun: those with four syllables, those denoting agents, and so on. But 'gender' is normally reserved for kinds or classes of noun that are, as Hockett (1958: 231) put it, "reflected in the behavior of associated words." To make valid comparisons, it is important to have this externally motivated classification. The relevant reflection in the behavior of associated words is 'agreement' (including for some linguists antecedent-anaphor relations). The noun inventory is divided into different kinds, or genders, according to the different agreements they take. When this is done, we find that in the more familiar languages, the different kinds or genders have a semantic core based on sex (thus, Russian nouns divide into three kinds; nouns denoting males, though not only these, group together, and those denoting females also group in another gender). In other languages the structures may be very similar, but the semantic core may not based not on sex; for instance, it may be based on human versus nonhuman or animate versus inanimate. Thus a language has a gender system only if noun phrases headed by nouns of different types control different agreements. No amount of marking on a noun can prove that it has gender; the evidence that nouns have gender in a given language lies in the agreement targets that show gender. An illustration of this from the Nakh-Daghestanian language Bagvalal (Kibrik, 2001: 64–65) will show this. Each noun in these examples is representative of many more:

(1) w-eša-w waša
MASC.SING-plump-MASC.SING boy
'a plump boy'

The word 'gender' derives from Latin *genus* via Old French *gendre,* originally meaning 'kind' or 'sort'. There are many kinds of noun: those with four syllables, those denoting agents, and so on. But 'gender' is normally reserved for kinds or classes of noun that are, as Hockett (1958: 231) put it, "reflected in the behavior of associated words." To make valid comparisons, it is important to have this externally motivated classification. The relevant reflection in the behavior of associated words is 'agreement' (including for some linguists antecedent-anaphor relations). The noun inventory is divided into different kinds, or genders, according to the different agreements they take. When this is done, we find that in the more familiar languages, the different kinds or genders have a semantic core based on sex (thus, Russian nouns divide into three kinds; nouns denoting males, though not only these, group together, and those denoting females also group in another gender). In other languages the structures may be very similar, but the semantic core may not based not on sex; for instance, it may be based on human versus nonhuman or animate versus inanimate. Thus a language has a gender system only if noun phrases headed by nouns of different types control different agreements. No amount of marking on a noun can prove that it has gender; the evidence that nouns have gender in a given language lies in the agreement targets that show gender. An illustration of this from the Nakh-Daghestanian language Bagvalal (Kibrik, 2001: 64–65) will show this. Each noun in these examples is representative of many more:

(1) w-eša-w waša
MASC.SING-plump-MASC.SING boy
'a plump boy'

(2) j-eša-j jaš
FEM.SING-plump-FEM.SING girl
'a plump girl'

(3) b-eša-b ʕama
NEUT.SING-plump-NEUT.SING donkey
'a plump donkey'

Attributive modifiers show that the nouns of Bagvalal divide into three agreement classes. In the plural, examples like (1) and (2) fall together, and so the plural does not yield additional agreement classes. No more does changing the case. Let us try changing the type of target, by looking at a verbal predicate:

(4) waša w-iRi
boy MASC.SING-stop
'the boy stopped'

(5) jaš j-iRi
girl FEM.SING-stop
'the girl stopped'

(6) ʕama b-iRi
donkey NEUT.SING-stop
'the donkey stopped'

Although the morphological realization is somewhat different (prefixal only instead of being prefixal and suffixal), the verbal predicate does not provide further agreement classes. Bagvalal has three agreement classes, and each should be recognized as a gender.

For languages in the Nakh-Daghestanian family, like Bagvalal, the term used is often 'noun classes.' But there is no substantive difference between 'genders' and 'noun classes'; the different terms arise in different linguistic traditions. For instance, Kannada (a Dravidian language) has three genders, to which nouns are assigned by rules similar to those of Bagvalal. By tradition, Kannada is said to have three genders, and Bagvalal three noun classes. We shall use the term 'gender' for both.

The Number of Genders

The approach to gender sketched in the first section of this article is based on the notion of 'agreement class' (Zaliznjak, 1964). For two nouns to be in the same agreement class, they must take the same agreements under all conditions – that is, if we hold constant other features such as case and number. (The agreements and their domains can be extremely varied; Corbett, forthcoming.) If two nouns differ in their agreements when factors such as case and number are held constant, then they belong to two different agreement classes and normally they will belong to two different genders. To take another example, in Russian, in environments where nominative singular forms are syntactically appropriate, nouns like *otec* 'father' and *stol* 'table' take the possessive adjective *moj* 'my' (*moj otec* 'my father'). Since this gender includes many nouns denoting males, it is conventionally labeled 'masculine,' even though the majority of nouns it includes, like *stol*, do not denote males. A second agreement class consists of nouns like *mat'* 'mother' and *kniga* 'book', which take *moja*, and make up the feminine gender. Finally, there are nouns like *pis'mo* 'letter', which take *moe*, and comprise the neuter gender.

For many languages there is no dispute as to the number of genders, but there are others where the question is complex. For instance, Romanian gender has provoked a lengthy debate. The analytical problem of determining the number of genders and the tests for deciding the gender of a given noun depend on separating out the sets into which nouns are divided (the 'controller genders') from the number of different genders marked on agreement targets (the 'target genders'). Frequently the two match up, as in French or German, but in several languages they do not. A full treatment of the subject is not possible here; for a detailed account and extensive references see Corbett (1991).

Gender Assignment

Given that there are the analytic means to establish the genders of a language and to determine which nouns belong in which gender, we now approach the question from the opposite perspective, and ask how nouns are allotted to the genders of a given language. In other words, how does a native speaker 'know' what gender a noun belongs to? Models of the mechanisms by which nouns are allotted to genders are called 'assignment systems.' Assignment may involve two sorts of information about the noun: its meaning and its form. To illustrate these, we will take some well-established clear examples. There are others that involve more complex combinations of systems.

Strict Semantic Assignment Systems

A strict semantic assignment system is found in Bagvalal (Kibrik, 2001: 64–66), as illustrated in the earlier examples. Nouns denoting male humans (and only those) are masculine, while those denoting female humans are feminine. All remaining nouns are neuter. Thus, *waša* 'boy' is masculine, *jaš* 'girl' is feminine, and *ʕama* 'donkey' is neuter. The meaning is sufficient, and no information about the form of a noun is needed to determine its gender. Kala Lagaw Ya, spoken on the Western Torres Straits Islands, has

a two-gender system, also with strict semantic assignment: nouns denoting males (and the moon, to which we return below) are masculine, and all others belong in the feminine gender (Bani, 1987). In Diyari (Dieri), a language of South Australia, we find the converse: there is a gender for nouns with female referents (such as women, girls, doe kangaroos), and the other gender is for all remaining nouns (Austin, 1981). Strict semantic systems are found in various parts of the world and are particularly prevalent in the Dravidian family, where there are three-gender systems (as in Kannada and Tamil) and two-gender systems (as in the Parji-Gadaba languages).

Predominantly Semantic Assignment Systems

Many languages have semantic assignment rules that are, however, less comprehensive than those of Bagvalal. Predominantly semantic assignment is found in Tsakhur, which like Bagvalal is a Nakh-Daghestanian language. Its four genders are shown in Table 1.

Assignment to genders I and II is straightforward: I is for male humans (also gods, angels, and so on), while II is for female humans (and female mythical beings). Most remaining animates are assigned to gender III, although a few belong to gender IV, along with some mythical beings. Inanimates are found in genders III and IV, and it is hard to discern a pattern (Mel'nikov and Kurbanov, 1964; Ibragimov, 1990: 54–56 and references there; Kibrik, 1999: 48–49).

Languages of this general type are widespread. For some of them, researchers have proposed that abstract semantic criteria partly miss the point, and that if we can gain a better grasp of the worldview of the speakers, we can then understand the assignment system more fully. The most discussed case is that of Dyirbal, North Queensland (Dixon, 1972), which has four genders, primarily for male humans and non-human animates (I), female humans (II), non-flesh food (III), and the residue (IV). There are various nouns for which additional principles are required. For example, the moon is in the first (masculine) gender and the sun is in the second (feminine) gender. This recalls Kala Lagaw Ya. In Dyirbal mythology, as indeed in much of Australia, the moon is the husband of the sun. For such instances, the mythological significance of referents can determine gender assignment. Dixon's data and analysis continue to provoke debate, and there is similar debate about the role of worldview in the gender assignment system of Ojibwa (and of other Algonquian languages of North America).

In all the languages discussed so far, the meaning of the noun determines gender. In the strict assignment systems, the rules are transparent; in the predominantly semantic systems, there are exceptions, although in some cases these may be explicable once the cultural setting is taken into account. If we ask which are the semantic criteria on which semantic systems can be based, we see recurring patterns. Quite often we find animate/inanimate, human/non-human, and male/female. Sometimes there is a gender for diminutives, as in various Bantu languages. There are also less usual genders, such as that for non–flesh food (Dyirbal) and the gender for insects (found in the Rikvani dialect of the Nakh-Daghestanian language Andi). A criterion that is sufficient to define a gender in one language may be just one factor in the assignment of gender in another. Thus the Bantu language Chichewa (a dialect of Nyanja) has a gender for diminutives, while in the Omotic language Dizi, diminutives together with nouns denoting females form a gender.

Table 1 Gender assignment in Tsakhur

Criterion	*Gender*	*Examples*	*Glosses*
Male rational	I (masculine)	*baba*	grandfather
		dak$_j$	father
Female rational	II (feminine)	*jed*$_j$	mother
		jiš	daughter
Animate (also some inanimates)	III (animate)	*aɪmale*	donkey
		balkan (*dama*) (*lat*)	horse (river) (trough)
Other (including a few animates)	IV (neuter)	*kalle*	head
		sen (*kabaj*)	year (butterfly)

Formal Assignment Systems

In many languages, the semantic rules assign many nouns to the appropriate gender, but they also simply fail to apply to many others. In Russian and in many other Indo-European languages, for sex-differentiables (those where sex is salient or of importance to humans), nouns denoting males are masculine and those denoting female are feminine. But these rules have nothing to say about the majority of the noun inventory. While in languages like Bagvalal, the nouns not assigned by the semantic rules (the 'remainder' or 'semantic residue') all belong to a single gender, in many languages they are found in more than one gender, even in all the genders (as in Russian). Here there are additional rules for assigning nouns to genders, but according to their form. Languages may use semantic rules, or semantic **and** formal rules, but not only formal assignment rules. In no language are

nouns assigned to genders, as defined earlier, by purely formal rules. An example would be a language in which there were two agreement classes, and the nouns in the first all ended in a consonant cluster, and those in the second did not, and there was no semantic regularity for the distribution of nouns. I claim that this hypothetical type does not exist. Formal assignment rules may appeal to two types of information: phonological and morphological.

Phonological The clearest example of assignment depending on phonological information yet found is provided by Qafar (Afar), an East Cushitic language spoken in northeastern Ethiopia and in Djibouti (data from Parker and Hayward, 1985). Qafar has rather standard semantic assignment rules, namely, that for sex-differentiable nouns, those denoting males are masculine and those denoting females are feminine. It is the nouns that fall outside these rules – the residue – that are of interest. For them the phonological rules apply: nouns whose citation form ends in an accented vowel are feminine (for example, *catò* 'help'), while all others are masculine (for example, *gilàl* 'winter', which does not end in a vowel, and *tàmu* 'taste', which ends in an unaccented vowel). These rules operate with few exceptions. There is an interesting twist here: nouns denoting males and females typically fit with the phonological assignment rules, too (for example, *bàqla* 'husband' and *barrà* 'woman, wife'). Given the data presented so far, we might try to dispense with semantic rules for Qafar and treat it as being of a quite different type. However, there are crucial examples like *abbà* 'father', which is masculine, even though it ends in an accented vowel. Similarly, *gabbixeèra* 'slender-waisted female' is feminine, even though the accent is not final. Qafar has straightforward phonological assignment rules. When the semantic and phonological rules are both applicable, they almost always give the same result in Qafar. However, in cases of conflict, the semantic rules take precedence, as is the normal situation in gender assignment systems. There are many more example of phonological assignment, although few if any are as clear as those of Qafar. At the other extreme we find French, often claimed to have no system to its gender assignment. Yet French has a phonological assignment system. For example, of 938 nouns ending in /ɛ̃/, 99 percent are masculine (*le pain* [pɛ̃] 'the bread') (for details see Tucker *et al.*, 1977; Hardison, 1992).

Morphological The morphological assignment system that has received the most attention is probably that of Russian. Earlier it was noted that in Russian, as in many other Indo-European languages, for sex-differentiables, nouns denoting males are masculine and those denoting females are feminine. But unlike the situation in languages like Bagvalal, the nouns not covered by these rules – the semantic residue – are not simply assigned to the neuter gender. Rather, in Russian, the residue is shared between the three genders, with the neuter gender not even receiving the majority. It seems unlikely that we are failing to spot additional semantic criteria; see (Table 2).

Table 2 Russian nouns belonging to the semantic residue

Masculine	*Feminine*	*Neuter*
dub 'oak'	***sosna*** 'pine'	*derevo* 'tree'
stvol '(tree) trunk'	*doska* 'plank'	***brevno*** 'log'
čaj 'tea'	*voda* 'water'	*moloko* 'milk'
ogon' 'fire'	*peč'* 'stove'	*plamja* 'flame'
okean 'ocean'	*reka* 'river'	*more* 'sea'
avtomobil' 'car'	*mašina* 'car'	*taksi* 'taxi'
den' 'day'	***noč'*** 'night'	*utro* 'morning'
čas 'hour'	*minuta* 'minute'	*vremja* 'time'
nerv 'nerve'	*kost'* 'bone'	*serdce* 'heart'
glaz 'eye'	*brov'* 'eyebrow'	*yeko* 'eyelid'
lokot' 'elbow'	*lodyžka* 'ankle'	*zapjast'e* 'wrist'
flag 'flag'	*èmblema* 'emblem'	*znamja* 'banner'

Nouns in bold are inflected in Table 3.

If the morphology of the nouns is examined instead, then progress can be made. There are arguably four main inflectional classes in Russian, each with several thousands of nouns. There are six cases and two numbers (although no paradigm has 12 distinct forms because of various syncretisms). Table 3 provides the singular forms.

Of course, a speaker needs to know the inflectional behavior of a noun. On the basis of that information, the assignment rules are straightforward. Nouns in inflection class I are masculine, those in classes II and III are feminine, and those in IV are neuter. As with Qafar, we might wonder whether the semantic assignment rules are superfluous, since *otec* 'father' is in class I, while *sestra* 'sister' is in class II, and *mat'* 'mother' is in class III, and therefore many sex-differentiable nouns would be assigned correctly by the morphological assignment rules. But there are also instances where this is not so. Thus, *deduška* 'grandfather' denotes a male but is in class II, whose nouns are typically feminine; it is masculine. Nouns like this show, once again, that we do not find languages where formal assignment rules are sufficient. Further rules are required in Russian for indeclinable nouns (like *taksi* 'taxi', which is indeclinable and neuter). Morphological assignment systems are found in various other Indo-European languages. Looking further afield, in Arabic, too, gender is assignable in the main according to morphology (Cowell, 1964:

Table 3 Inflectional classes in Russian

	I	*II*	*III*	*IV*
Nominative	*dub*	*sosna*	*noč'*	*brevno*
Accusative	*dub*	*sosnu*	*noč'*	*brevno*
Genitive	*duba*	*sosny*	*noči*	*brevna*
Dative	*dubu*	*sosne*	*noči*	*brevnu*
Instrumental	*dubom*	*sosnoj*	*noč'ju*	*brevnom*
Locative	*dube*	*sosne*	*noči*	*brevne*
Gloss	'oak'	'pine'	'night'	'log'

372–375). In Kuot, a language isolate of New Ireland, Lindström (2002: 147–164, 176–194) suggested that there were 11 inflectional classes for nouns, and the assignment of nouns to the two genders could be predicted to a significant extent on the basis of the inflectional class (in addition to a semantic rule based on sex).

The clearest examples have been chosen here for illustration. In some languages, the different types of assignment criteria overlap and interact in complex ways. Sometimes there are small clusters of nouns subject to semantic criteria (apart from those covered by the main semantic rules), even within systems where formal rules have a major role (as shown for German by Zubin and Köpcke, 1986; Köpcke and Zubin, 1996). Even in these complex cases, whenever gender languages are analyzed in sufficient detail, the gender of the vast majority of nouns turns out to be predictable.

Distribution

Given this typology of gender systems, we can now ask how they are distributed over the world's languages. In a sample of 256 languages (Corbett, 2005), somewhat over half (144) were found to have no gender system. A gender system with at least two genders (and two-gender systems are common) existed in 50 examples in this sample. Three genders was about half as common (26 examples), and four genders was about half as common again (12 examples). Larger systems, with five or more genders, represented a substantial minority (24 languages in the sample). Fula (a Niger-Congo language) has around 20 genders, depending on the dialect. Of the languages with a gender system, the majority had an assignment system based on sex (84 examples), but 28 languages of the sample, notably in the Niger-Congo and Algonquian families, had systems based on animacy. And as for the type of assignment system, strict semantic and predominantly assignment systems together were found in just under half the languages (53 examples), while a slight majority (59 examples) had semantic and formal assignment.

Prospects

Studies on grammatical gender continue to appear regularly. There are four areas in which we can hope for progress.

Data

Studies of previously unresearched or little-researched languages continue to extend our knowledge of gender systems. For example, in Ngan 'gityemerri a Daly language spoken in northern Australia) there is a development from generic classifiers into genders (Reid, 1997); a comparable situation, but with a very large system, is found in Miraña (Boa), a Witotoan language spoken in Colombia, as described by Seifart (2004). It is possible to have gender and classifier systems co-existing, as in Tariana (Aikhenvald, 2003). Among the better known languages, some studies of gender are based on a few convenient parts, while fuller studies of the whole morphosyntax, to the extent that it is relevant to gender, and of a substantial portion of the lexicon, can contribute significantly to our understanding of gender. The incorporation of loanwords can be seen as a continuously running experiment on an assignment system, offering the possibilities for statistical analysis, as in Kilarski's (2003) account of English borrowings into Danish, Norwegian, and Swedish.

Lexicology

Gender is a key feature for lexicology, since it is crucial for understanding the nature of lexical entries. In a gendered language, the gender of a noun must be available. Yet as we have seen, it does not normally need to be specified, since the information can be derived, by assignment rules, from other information that must be stored. We still do not know the full range of information that may be relevant (for instance, the possible semantic features that may determine gender assignment). There are further surprises: it is possible for certain nouns to be of different genders according to the sex of the speaker; this is found in Garífuna, a member of the Arawak language family spoken in Belize, Honduras, Nicaragua, and Guatemala (Taylor, 1977: 60; Munro, 1998). These two points raise interesting questions as to the shape of lexical entries.

Psycholinguistics

The issues specified for lexicologists are also increasingly of concern to psycholinguists (see, for instance, van Berkum, 1996). Gender provides a feature that is moderately well described, typically has few values, and yet is pervasive in one language and absent in

another, thus providing helpful control conditions. Psycholinguists are also interested in apparently non-linguist effects of grammatical gender, as in judgments of picture similarity (see Boroditsky *et al.*, 2003). There has been some interesting work on how children acquire gender systems by Mills (1986) and Müller (2000), among others. Such studies may also help us to see how such systems change over time, as shown by the work of Polinsky and Jackson (1999) on Tsez (Dido); see also Comrie and Polinsky (1998). For further work on modeling of change in assignment systems see Polinsky and Everbroeck (2003). An account of the history of gender in Indo-European is provided by Matasović (2004).

Modeling

Modeling is being used in various ways. First, it is used to verify particular analyses. Some types of assignment system are so transparent that alternative analyses are hard to imagine. However, with morphological assignment systems, particularly when the number of genders and the number of inflectional classes are close in a given language, there are other possible analyses. Arguments in favor of the morphological approach include the following: the main claim is that in languages like Russian, the internal evidence shows that we can assign gender from inflectional class (but the inflectional class cannot be predicted from gender); second, there is the typological claim that one of the possible types of assignment system (or some combination) will always guarantee that gender is predictable for the vast majority of nouns, and so treating the Russian type system differently would create an anomaly. However, modeling allows us to take a further step. Fraser and Corbett (1995) employed the Network Morphology framework to give an account of the Russian gender and inflectional class relations. Since the analysis was implemented in the lexical knowledge representation language DATR (Evans and Gazdar, 1996), the analyses can be verified computationally. It can be demonstrated that, starting from minimal lexical entries for a wide range of nouns, this account did indeed predict the right genders.

A more complex situation is found in languages where gender is assigned according to morphological class, but where the morphological class is itself predictable. A well-studied case is Bumbita Arapesh, a language of the Toricelli family spoken on the north coast of New Guinea (Fortune, 1942; Aronoff, 1992; 1994: 89–114). In addition to semantic assignment rules based on sex, there are morphological assignment rules that determine 13 genders on the basis of 22 morphological classes, and the latter are largely predictable from phonological information. It has been demonstrated how this system can be analyzed within the Network Morphology framework, and an implementation has been provided to demonstrate that these claims are indeed valid (Fraser and Corbett, 1997). There is also a complex interaction of assignment to gender and to morphological class in Bininj Gun-Wok (previously Mayali), a non-Pama-Nyungan language of northern Australia, which has four genders and five morphological classes for nouns. This too has been successfully implemented; for details of a formal model of this system see Evans *et al.* (2002). Modeling has tended to concentrate on synchronic assignment systems. However, there is also interesting work on modeling the development of assignment systems over time, as in Polinsky and Everbroeck (2003), as noted earlier.

Conclusion

We have seen why gender continues to evoke such interest: it is a core feature in some languages, while in many others it is absent. We have the analytic tools for investigating gender systems, and new and intriguingly complex systems are still coming to light. In terms of gender assignment, the rules vary from being fully transparent, as in Bagvalal, to complex, as in French and German. It is a research area in which various different types of expertise are leading to gradual progress.

Gender, Sexuality and Language

M Bucholtz, University of California, Santa Barbara, Santa Barbara, CA, USA
K Hall, University of Colorado, Boulder, CO, USA

© 2006 Elsevier Ltd. All rights reserved.

Gender initially became a focus of linguistic interest in the first half of the 20th century when field linguists discovered what they perceived as stark differences between European languages and the indigenous languages they had begun to document in the Americas and elsewhere. Of particular interest was the finding that a number of these languages differentiated between women's and men's speech on the basis of grammar, phonology, and lexicon. These so-called 'women's languages' and 'men's languages' were characterized as vastly different and mutually exclusive, and were often held up as evidence for the rigidity of gender roles in traditional societies in contrast to the enlightened gender liberalism of Western modernity. In addition to the problematic exoticism of native languages and cultures that informs this view, such a dichotomy between traditional and modern structures of gender is empirically untenable. It has recently been shown, for instance, that it was only under the conditions of modernization that gender differentiation through the creation of 'women's language' emerged in Japan.

In these early texts, sexuality was not theoretically distinguished from gender; researchers assumed a direct mapping from one to the other and of both onto language. Thus a speaker's departure from normative speech patterns was interpreted as gender deviance as well as sexual deviance, with 'effeminate' and 'bisexual' speakers occupying the margins as linguistic exceptions to an otherwise unyielding gender dichotomy. What was missing from such a perspective was the concept of 'indexicality,' the process whereby language 'points to' the social and discursive context of its own production. Seen in this way, many instances of perceived cross-gender language use might more accurately be understood as indexing interactional stances such as affect or force/mitigation, not gender identities.

Despite its flaws, the early anthropological research on women's and men's languages did call attention to the important relationship between gender and sexuality. However, this connection was not developed theoretically until the 1990s, in spite of the small but steady stream of linguistic publications on sexuality. In the 1970s, a number of ethnographically oriented researchers published a flurry of studies on sexualized insults and banter, focusing primarily on male speakers. Although the intention of such work was to bring underinvestigated communities and genres into linguistic scholarship, many of these studies unwittingly worked to reinscribe stereotypes of the licentious and hypersexed Other.

As linguistic anthropologists began to turn their attention to at least some aspects of sexuality, gender was gaining a more central role in linguistic scholarship due to the influence of second-wave feminism, especially in sociolinguistic research on Western languages. One of the earliest and most important contributions to this new line of feminist scholarship offered a different conceptualization of 'women's language' as primarily pragmatic rather than structural and suggested that women's speech both produced and reflected real-world powerlessness. This view was complicated by contemporary anthropological research, however, which revealed that women's speech in other cultures could be forceful and assertive, though still devalued.

Recognizing the widespread deprecation of social practices associated with women, by the 1980s many feminist social scientists, including linguistic anthropologists, were seeking to validate women as competent cultural members in their own right. Meanwhile, the concept of 'culture' was adopted by some researchers of American society to account for what were still seen as vast differences between women and men. Though inspired by anthropological work on cross-cultural communication, this body of work overlooked widespread efforts to rethink the concept of culture within anthropology in this period.

Gender initially became a focus of linguistic interest in the first half of the 20th century when field linguists discovered what they perceived as stark differences between European languages and the indigenous languages they had begun to document in the Americas and elsewhere. Of particular interest was the finding that a number of these languages differentiated between women's and men's speech on the basis of grammar, phonology, and lexicon. These so-called 'women's languages' and 'men's languages' were characterized as vastly different and mutually exclusive, and were often held up as evidence for the rigidity of gender roles in traditional societies in contrast to the enlightened gender liberalism of Western modernity. In addition to the problematic exoticism of native languages and cultures that informs this view, such a dichotomy between traditional and modern structures of gender is empirically untenable. It has recently been shown, for instance, that it was only under the conditions of modernization that gender differentiation through the creation of 'women's language' emerged in Japan.

In these early texts, sexuality was not theoretically distinguished from gender; researchers assumed a direct mapping from one to the other and of both onto language. Thus a speaker's departure from normative speech patterns was interpreted as gender deviance as well as sexual deviance, with 'effeminate' and 'bisexual' speakers occupying the margins as linguistic exceptions to an otherwise unyielding gender dichotomy. What was missing from such a perspective was the concept of 'indexicality,' the process whereby language 'points to' the social and discursive context of its own production. Seen in this way, many instances of perceived cross-gender language use might more accurately be understood as indexing interactional stances such as affect or force/mitigation, not gender identities.

Despite its flaws, the early anthropological research on women's and men's languages did call attention to the important relationship between gender and sexuality. However, this connection was not developed theoretically until the 1990s, in spite of the small but steady stream of linguistic publications on sexuality. In the 1970s, a number of ethnographically oriented researchers published a flurry of studies on sexualized insults and banter, focusing primarily on male speakers. Although the intention of such work was to bring underinvestigated communities and genres into linguistic scholarship, many of these studies unwittingly worked to reinscribe stereotypes of the licentious and hypersexed Other.

As linguistic anthropologists began to turn their attention to at least some aspects of sexuality, gender was gaining a more central role in linguistic scholarship due to the influence of second-wave feminism, especially in sociolinguistic research on Western languages. One of the earliest and most important contributions to this new line of feminist scholarship offered a different conceptualization of 'women's language' as primarily pragmatic rather than structural and suggested that women's speech both produced and reflected real-world powerlessness. This view was complicated by contemporary anthropological research, however, which revealed that women's speech in other cultures could be forceful and assertive, though still devalued.

Recognizing the widespread deprecation of social practices associated with women, by the 1980s many feminist social scientists, including linguistic anthropologists, were seeking to validate women as competent cultural members in their own right. Meanwhile, the concept of 'culture' was adopted by some researchers of American society to account for what were still seen as vast differences between women and men. Though inspired by anthropological work on cross-cultural communication, this body of work overlooked widespread efforts to rethink the concept of culture within anthropology in this period.

A more complex understanding of culture emerged in language and gender research in the next decade, accompanied by more explicit theorizing of the concept of gender.

Much research on gender and language from the 1990s to the present has been greatly enriched by attention to the ideological symbolic aspects of talk as produced within particular communities of practice. In language and gender research, these insights led scholars to set aside a monolithic model of women's gender identity in favor of an examination of diverse versions of femininity even within a single 'culture' such as the United States.

Developments in poststructuralist gender theory and queer theory have further contributed to this shift. Drawing on and revising the poststructuralist feminist concept of performativity, which borrows heavily from the concept of the performative in the philosophy of language, linguistic anthropologists have documented the linguistic practices of gender-transgressive and sexually marginalized social groups around the world. Some of this research has been positioned within the theoretical perspective now known as 'queer linguistics,' which focuses on how sexuality is regulated by hegemonic heterosexuality and how nonnormative sexualities are negotiated in relation to such regulatory structures. Recent scholarship has considered how such groups use language to index varying stances of modernity and tradition in the context of postcolonialism and globalization.

In addition to the new focus on such groups, many of which have been understudied due to their social marginalization, linguists have also turned to those aspects of gender and sexuality that have gone uninvestigated due to their unmarked and hegemonic status, namely, masculinity and heterosexuality. The ethnographic study of desire has likewise received more attention in linguistic anthropology, as scholars have begun to consider the ways in which romance and eroticism are both produced and constrained socioculturally. Newer research on sexual joking shares this ethnographic focus, analyzing linguistic humor as a product of localized understandings of power, marginality, and socioeconomic class.

There has recently been a vociferous call to reframe the field of language and sexuality more narrowly in terms of psychoanalytically construed desire rather than sexual identity. The recent explosion of scholarship on a variety of compelling topics, however, including a more richly theorized concept of identity, suggests that the field's boundaries will continue to expand rather than contract. The intersection of sexuality with phenomena such as globalization, life stage, asexuality, health, and bilingualism, for instance, has only recently begun to receive linguistic attention. Currently, language, gender, and sexuality is a vibrant and dynamic area of research that is increasingly shedding its formerly marginal status to become a central empirical and theoretical contributor to the field of linguistic anthropology.

General Semantics

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

General semantics was initiated by Korzybski (Korzybski, 1958 [1933, 1938, 1948]) and propagated through the journal *ETC.*, by Chase (Chase, 1938, 1954) and by Hayakawa (Hayakawa, 1972 [1949, 1964]). Its aims are "The study and improvement of human evaluative processes with special emphasis on the relation to signs and symbols, including language" (Chase, 1954: 128). Korzybski wrote:

> The present-day theories of 'meaning' are extremely confused and difficult, ultimately hopeless, and probably harmful to the sanity of the human race.
>
> . . .
>
> There is a fundamental confusion between the notion of the older term *semantics* as connected with a theory of verbal 'meaning' and words defined by words, and the present theoretical term *general semantics,* which deals only with *neuro*semantic and *neuro*linguistic *living reactions* of Smith_1, Smith_2, etc., as their reactions to neurosemantic and neurolinguistic *environments as environment* (Korzybski, 1958: xxx).

General semantics was (and is) supposed to have therapeutic value: "In general semantics we utilize what I call 'neuro-semantic relaxation,' which, as attested by physicians, usually brings about 'normal' blood pressure" (Korzybski, 1958: xlvii) – but no attestations are in fact supplied. The heir to semantics-as-therapy is neuro-linguistic programming (Bandler and Grinder, 1975, 1979, 1982; Grinder and Bandler, 1976; O'Connor and Seymour, 1990).

General semantics has a mission to educate people against the dangers of being hoodwinked by propaganda, euphemism, gobbledygook, and even ordinary, everyday language. In part, the movement was a response to the affective and all too effective jargon of 20th century European totalitarianism (both fascism and communism) and of McCarthyism in the United States. So a constant theme is "Don't be bamboozled by what is said, search for the meaning and substance in all that you hear." Bolinger blames general semantics for giving rise to the jibe *That's just semantics* in which the word *semantics* has the sense 'pettifogging' (Bolinger, 1980: vii).

General semantics "tells you *what to do* and *what to observe* in order to bring the thing defined or its effects within the range of one's experience" (Hayakawa, 1972: 157). More precisely, the literal meaning of a statement expressed by sentence Σ is given by defining the method for observationally verifying the conditions under which Σ is properly used. There are several problems with this method. First, as Ayer (Ayer, 1946: 12) admits, there is no upper limit on the number of conditions on Σ's use. Second, verificationism interprets "conditions under which Σ is properly used" as "conditions under which the truth of the statement expressed by Σ is true"; consequently, values other than truth must be found for types of illocutionary acts such as requestives, directives, expressives, permissives, and declarations. Third, Hayakawa (Hayakawa, 1972: 54) contrasts the simplicity of using a tapemeasure to verify the truth of *This room is fifteen feet long* with the impossibility of operationally verifying to everyone's satisfaction *Angels watch over my bed at night* or *Ed thinks he dreamt he was in bed with Marilyn Monroe*. Such sentences are judged meaningless and therefore synonymous with one another – which they are not. Fourth, operational semantics affords no account of the compositionality of meaning. Fifth, general semantics has little or nothing to say about semantic relationships within a language.

In sum, general semantics has little to offer the 21st century linguist; but for what it does offer, check out the Institute of General Semantics.

Generalization

E Mathieu, University of Ottawa, Ottawa, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Linguists make generalizations: that is what they do for a living. To make a generalization means having a look at a set of phenomena, for example a set of sentences, a set of sounds, and seeing what they have in common. First, one needs to describe and analyze data accurately, and then one needs to generalize over those data. Concentrating on word order and the status of 'subject,' consider the Old French (OF) example in (1) as a way of illustration.

(1) et li baron regardent les letres.
and the barons look at the letters
'The barons look at the inscription.' (*La Queste del Saint-Graal*, 5, 22)

In (1), we note that the order is Subject-Verb-Object (subject = *li baron*; verb = *regardent*; object = *les letres*). This is the first observation we make about OF word order. In (2), we see, however, that the situation is slightly more complicated.

(2) ceste costume ai je toz jors tenues.
this habit have I all days held
'I have always held this habit.' (*La Queste del Saint Graal*, 5, 7)

In this example, the subject (*je*) is postverbal while the object (ceste costume) is preverbal. The question that arises is thus: is French an SVO language (i.e., with Subject-Verb-Object order) or an OVS language (i.e., with Object-Verb-Subject order)? If we were to look at a corpus of OF texts, we would note that there are no attested cases where the subject is postverbal without the presence of an element in the preverbal zone. All sorts of elements can appear in that position always forcing the verb to be in the second position, hence the term used for such configurations: **V2** (most commonly associated with languages like German).

Thus, our first generalization is the following: in OF the subject is preverbal, except in cases where the preverbal position is occupied by something else.

Now, let us consider a second generalization in connection with the first. In OF, referential and non-referential subjects were possible, but a special environment was necessary for them to be licensed. Whereas Spanish and Italian allow a null subject in contexts such as (3), OF does not. (3) is an example from Spanish.

(3) habla español.
speak-3SG.PRES Spanish
'He/she speaks Spanish.'

Traditionally, the fact that languages like Spanish and Italian allow null subjects is explained by the fact that rich inflection is present on the verb (this inflection has a pronominal property and can 'stand for' the nominal). OF did not have uniform (i.e., for all persons across tenses) rich agreement (cf. Roberts,

Generalization

E Mathieu, University of Ottawa, Ottawa, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Linguists make generalizations: that is what they do for a living. To make a generalization means having a look at a set of phenomena, for example a set of sentences, a set of sounds, and seeing what they have in common. First, one needs to describe and analyze data accurately, and then one needs to generalize over those data. Concentrating on word order and the status of 'subject,' consider the Old French (OF) example in (1) as a way of illustration.

(1) et li baron regardent les letres.
and the barons look at the letters
'The barons look at the inscription.' (*La Queste del Saint-Graal*, 5, 22)

In (1), we note that the order is Subject-Verb-Object (subject = *li baron*; verb = *regardent*; object = *les letres*). This is the first observation we make about OF word order. In (2), we see, however, that the situation is slightly more complicated.

(2) ceste costume ai je toz jors tenues.
this habit have I all days held
'I have always held this habit.' (*La Queste del Saint Graal*, 5, 7)

In this example, the subject (*je*) is postverbal while the object (ceste costume) is preverbal. The question that arises is thus: is French an SVO language (i.e., with Subject-Verb-Object order) or an OVS language (i.e., with Object-Verb-Subject order)? If we were to look at a corpus of OF texts, we would note that there are no attested cases where the subject is postverbal without the presence of an element in the preverbal zone. All sorts of elements can appear in that position always forcing the verb to be in the second position, hence the term used for such configurations: **V2** (most commonly associated with languages like German).

Thus, our first generalization is the following: in OF the subject is preverbal, except in cases where the preverbal position is occupied by something else.

Now, let us consider a second generalization in connection with the first. In OF, referential and non-referential subjects were possible, but a special environment was necessary for them to be licensed. Whereas Spanish and Italian allow a null subject in contexts such as (3), OF does not. (3) is an example from Spanish.

(3) habla español.
speak-3SG.PRES Spanish
'He/she speaks Spanish.'

Traditionally, the fact that languages like Spanish and Italian allow null subjects is explained by the fact that rich inflection is present on the verb (this inflection has a pronominal property and can 'stand for' the nominal). OF did not have uniform (i.e., for all persons across tenses) rich agreement (cf. Roberts,

1993), which might explain why null subjects were not possible in environments such as (3).

However, if we look at a series of texts in OF we note that there are plenty of attested examples with null subjects.

(4) lors vienen a un huis barré.
then came to a gate
'Then they came to a gate (a postern).' (*Le Chevalier à la Charrette* 2368)

The question is now: how are these null subjects licensed? Looking closely at the data, we note that the structure is a V2 configuration (there is an element appearing before the verb). Thus, the generalization must be that null subjects in OF are possible provided non-subject material appears in the preverbal position and that the verb is in second place.

In order to go beyond simple description of the data, the next step after a generalization is to make a hypothesis that will make predictions. We know from numerous sources that OF was a so-called asymmetric V2 language, i.e., allowed V2 only in main clauses (some languages, such as Yiddish or Icelandic, are symmetric V2 languages). Since we have established that null subjects in OF were licensed in/by a V2 environment, we predict, that is, make the hypothesis, that null subjects are not possible in OF embedded clauses. This is generally believed to be the case. We thus find some confirmation for our hypothesis.

However, a hypothesis is a hypothesis is a hypothesis. It has been argued that some embedded environments allowed null subjects in OF. There are cases of null referential subjects in interrogative and adverbial embedded clauses in a range of 12th-century prose and verse texts, as well as in some 13th-century verse texts (Hirschbühler, 1990). Consider the following two examples where __ indicates a subject gap.

(5) a. por l'esperance qu'an
for the-hope which-in
lui __ ont, . . .
him have.3PL.PRES . . .
'For the hope which they have in him, . . .'
b. et si ne sait
and so not knows.3SG.PRES
que faire __ puisse.
what do-INF can.3SG.SUBJ
'And so he doesn't know what he can do.'

When making a generalization, however, one should be careful. Although (5a) and (5b) appear to involve V2 at first (*an lui* appears before the verb in the first example while *faire* appears before the verb in the second), it has been argued that in fact they do not. Such cases are not cases of topicalization, that is, V2, but of so-called 'stylistic fronting' (Cardinaletti and Roberts, 1991/2002). There are clear differences between topicalization of the V2 kind and stylistic fronting (see Maling, 1980 and also Holmberg, 2000 for details).

The idea that we are not dealing with topicalization is strengthened by the fact that null subjects are possible in non-interrogative embedded clauses without inversion of the verb as shown, for example, by Adams (1987a, 1987b), Dupuis (1988, 1989), Hirschbühler and Junker (1988), Vance (1988) and Hirschbühler (1990).

(6) a. je suis le sire a cui __
I am the lord to whom (you)
volez parler.
wish-2PL.PRES speak-INF
'I am the lord to whom you wish to speak.'
(*Aymeri de Narbonne* 4041, in Hirschbühler, 1990: 36)
b. l'espee dont __ s'estoist
the-sword by-which self-was.3SG.PAST
ocis
killed
'The sword with which he killed himself.'
(*Chastelaine de Vergi* 913, in Hirschbühler, 1990: 36)
c. ainz que __ m'en aille
thus that myself-pro go.1SG.SUBJ
en France
in France
'Thus that I go to France.'
(*Aymeri de Narbonne* 204, in Hirschbühler, 1990: 36)
d. quant__ vit le roi
when saw.3SG.PAST the king
'When he saw the king.'
(*Aymeri de Narbonne* 702, in Hirschbühler, 1990: 36)

These examples show that at some point French seemed to be developing a system according to which null subjects no longer require V2 to be licensed. However, it is unlikely that French developed a system resembling that of Spanish and Italian. This is because the inflections on the verb did not suddenly become (uniformly) rich. Therefore, the licensing of null subjects in environments such as (6) still remains something of a mystery.

In conclusion, a generalization is always very fragile in that counterexamples are often easy to find. The important point is that in order to make progress in the search for patterns, one should not be afraid of

dropping previous generalizations in order to make new ones.

Generating Referring Expressions

R Dale, Macquarie University, Sydney, NSW, Australia

Introduction: An Informal Characterization of the Problem

The generation of referring expressions is a key component task in many studies of natural language generation, and one that has attracted a significant amount of attention over the past 15–20 years. Every natural language generation system has to talk about things, and in order to do so it has to determine how to refer to the things it wants to talk about. This may seem relatively straightforward when the entities to be talked about have names or possess other unique identifiers – so-called **rigid designators** (Kripke, 1980) – as is the case for people and certain other special types of entities, such as cities, newspapers, or ships. In such cases, we can usually assume that the use of the name or identifier will be enough to pick out the entity in question. However, most entities in the world do not have unique names; in the absence of a unique name, in order to refer to such an entity, the generator is faced with the task of constructing a description that allows the hearer to identify the intended referent. The process is necessarily a constructive one, or at least one of choice among a number of possibilities, since what counts as an appropriate form of reference will depend on contextual factors. Determining what description to use is the problem of referring expression generation.

As human users of a natural language, we are faced with this task countless times every day. Suppose, for example, we are in a meeting, and I am drawing a diagram on a whiteboard. While carrying out this exercise, I discover that I need to use a different color to highlight some aspect of my diagram, and so I decide to ask you to pass me a particular whiteboard pen that is out of my reach on the other side of the table. If there are a number of other whiteboard pens on the table, and other ones scattered around the room in other locations, a bare request of the form *Could you pass me the whiteboard pen?* is unlikely to do the job. I need to identify for you the particular pen I want you to pass to me, and to do so, in the

dropping previous generalizations in order to make new ones.

Generating Referring Expressions

R Dale, Macquarie University, Sydney, NSW, Australia

© 2006 Elsevier Ltd. All rights reserved.

Introduction: An Informal Characterization of the Problem

The generation of referring expressions is a key component task in many studies of natural language generation, and one that has attracted a significant amount of attention over the past 15–20 years. Every natural language generation system has to talk about things, and in order to do so it has to determine how to refer to the things it wants to talk about. This may seem relatively straightforward when the entities to be talked about have names or possess other unique identifiers – so-called **rigid designators** (Kripke, 1980) – as is the case for people and certain other special types of entities, such as cities, newspapers, or ships. In such cases, we can usually assume that the use of the name or identifier will be enough to pick out the entity in question. However, most entities in the world do not have unique names; in the absence of a unique name, in order to refer to such an entity, the generator is faced with the task of constructing a description that allows the hearer to identify the intended referent. The process is necessarily a constructive one, or at least one of choice among a number of possibilities, since what counts as an appropriate form of reference will depend on contextual factors. Determining what description to use is the problem of referring expression generation.

As human users of a natural language, we are faced with this task countless times every day. Suppose, for example, we are in a meeting, and I am drawing a diagram on a whiteboard. While carrying out this exercise, I discover that I need to use a different color to highlight some aspect of my diagram, and so I decide to ask you to pass me a particular whiteboard pen that is out of my reach on the other side of the table. If there are a number of other whiteboard pens on the table, and other ones scattered around the room in other locations, a bare request of the form *Could you pass me the whiteboard pen?* is unlikely to do the job. I need to identify for you the particular pen I want you to pass to me, and to do so, in the

absence of an associated pointing gesture – suppose both my hands are occupied – I need to formulate a verbal description of this pen that allows you to determine which pen I have in mind. The pen has many properties that I could use in such a description, including some that are intrinsic to the pen (the fact that it is red, that it is of a particular brand, and so on), and some that it possesses by virtue of its relationship to other entities (the fact that it is nearer to you than it is to another colleague, the fact that it is on the table rather than on the floor, and so on). Which of these properties it is most appropriate to use in my description will depend on a range of contextual factors, including what other entities are in the environment, and what knowledge I might believe you to have of the entity in question. For example, I might say *Could you pass me the pen that Bill brought yesterday?* but this is appropriate only if I have reason to believe that you are aware of the provenance of the pen. Of course, as humans, we are normally able to carry out the task of producing an appropriate and effective identifying description with apparent effortlessness. The goal of researchers interested in natural language generation is to design algorithms that can achieve the same end results.

A More Formal Characterization of the Problem

From the point of view of computational implementation, natural language generation (NLG) is generally conceived of as a process that involves many subtasks, including **content determination**, **text planning**, **sentence planning**, **lexicalization**, and **grammatical realization**. Yorick Wilks is credited with the observation that, if natural language understanding is like counting from one to infinity, then natural language generation is like counting from infinity to one: in every one of the subtasks that make up NLG, a key problem that presents itself is the question of what kind of input to take as a starting point. For each subtask, the lack of an agreed consensus on the answer to this question is a major stumbling block to the consolidation of research results from different perspectives. For example, it is difficult to compare the merits of two components that carry out grammatical realization – the process of producing a syntactic structure, given some input semantic structure that contains the content to be conveyed – if the two components embody different views as to what a semantic structure should contain. The task of referring expression generation stands out from among these other subtasks in that there is a widely agreed starting point. It is probably this fact more than any other that has contributed to the level of interest in addressing this particular research problem.

The bulk of research in the generation of referring expressions takes as given the following assumptions:

- We have a domain that consists of a collection of entities, identified by symbolic identifiers, such as e_1 through e_n.
- The entities in the domain are characterized in terms of a set of attributes and the values that the entities have for these attributes; so, for example, our knowledge base might represent the fact that entity e_1 has the value pen for the attribute type, and the value red for the attribute color, where the symbols used to designate attribute values correspond to conceptual or semantic elements rather than to surface lexical items. We will use the notation ⟨*attribute*, *value*⟩ for attribute–value pairs; for example, ⟨color, red⟩ indicates the attribute of color with the value red.
- In a typical context, when we want to refer to some e_1, which we call the intended referent, there will be other entities from which the **intended referent** must be distinguished; these are generally referred to as **potential distractors**.

The goal of referring expression generation is therefore to find some collection of attributes and their values that distinguish the intended referent from all of the potential distractors in the context. If such a collection of attributes and their values can be found, then it serves as a **distinguishing description**. Formally, we can characterize this as follows:

> Let r be the intended referent, and C be the set of distractors; then, a set L of attribute–value pairs will represent a distinguishing description if the following two conditions hold:
> - C1: Every attribute–value pair in L applies to r: that is, every element of L specifies an attribute–value that r possesses.
> - C2: For every member c of C, there is at least one element l of L that does not apply to c: that is, there is an l in L that specifies an attribute value that c does not possess; l is said to *rule out* c.

We can think of the generation of referring expressions as being governed by three principles, referred to by Dale (1992) as the principles of **adequacy**, **efficiency**, and **sensitivity**; these are Gricean-like conversational maxims (Grice, 1975) framed from the point of view of the specific task of generating referring expressions. The first two of these principles are primarily concerned with saying neither too much nor too little: the principle of adequacy requires that a

referring expression should contain enough information to allow the hearer to identify the referent, and the principle of efficiency requires that the referring expression should not contain unnecessary information. The principle of sensitivity, however, has a different concern: it specifies that the referring expression constructed should be sensitive to the needs and abilities of the hearer or reader. Accordingly, the definition of a distinguishing description specified here should really include a third component:

- C3: The hearer knows or can easily perceive that conditions C1 and C2 hold.

In other words, the hearer must realize that the distinguishing description matches the intended referent and none of the potential distractors, and ideally this realization should not require a large perceptual or cognitive effort on the hearer's part.

In broad terms, the task of referring expression generation is assumed to fall within the overall architecture of a natural language generation system in the following manner. We generally assume that some prior stage of processing has determined what speech acts and embedded propositions should be expressed in the surface form output, whether written or spoken. For example, the referring expression generator might be invoked when we have an input structure corresponding to something like request(h, pass(h, s, e_1)), where h is the hearer, s is the speaker, and e_1 is some entity: in other words, the speaker has determined that it wants to produce an utterance that requests the hearer to pass the speaker the entity in question. An appropriate utterance corresponding to this structure might begin *Please pass me* . . . . The provenance of the input structure is not considered to be of relevance to the task of referring expression generation, but typically is the responsibility of the sentence-planning component, and linguistic realization will be responsible for fleshing out the embedded proposition in an appropriate syntactic form, such as the request described here. The task of referring expression generation is to decide how to refer to the entities in the proposition. Note that, strictly speaking, this includes determining how to refer to both the hearer and the speaker. The chosen syntactic form in this case rules out the need for an explicit reference to the hearer, and we will assume that the choice of the third-person singular personal pronoun to refer to the speaker is straightforward; in reality, however, things may not always be so simple.

If we leave aside those cases in which the intended referent has a unique name, the task can be thought of, in Fregean terms, as mapping from a referent to something like a sense (Frege, 1892). Generally speaking, the output of the process is seen as being a fragment of semantic content, rather than as a collection of lexical elements; the lexicalization of the chosen semantic material is considered to be a separate and subsequent task. This allows the later process to make further and more surface-oriented choices; for example, once the content of a description has been chosen, surface realization might then still have the option of realizing that description as either *the red pen* or *the pen that is red*. This view makes the referring expression generation task one of content determination, and raises some questions as to where this process is best located within the natural language generation task as a whole: generally, we think of content determination as having taken place before (for example, sentence planning). This question and its ramifications merit further exploration, but this is beyond the scope of this article.

Approaches to the Problem

Early Work

As noted previously, the generation of referring expressions is a component task in almost all NLG systems. Discussion of issues that arise in the broader context of NLG system construction can be found in the seminal early works of Davey (1979), McDonald (1980), and McKeown (1985). However, in each of these cases, the generation of referring expressions was only one of many tasks the authors tried to address, and so the problem was necessarily only touched on, and not given an extensive treatment. The first major work to look specifically at the problem of referring expression generation was that of Appelt (1985). This work contained many insights into the range of problems that a thoroughgoing solution to the problem needs to consider, placing the task firmly within the framework of speech acts (Searle, 1969). Following other work that has attempted to model speech acts by means of artificial intelligence (AI)-style planning operators, Appelt developed a plan-based approach to constructing references, whereby the speaker reasons about the effects on the hearer by using particular elements of content in a referring expression.

Producing Minimal Distinguishing Descriptions

The early works of Davey, McDonald, McKeown, and Appelt clearly established the need to view the generation of referring expressions as a specific task

to be addressed within a generation system. However, none of these works provided a formally well-specified algorithm for carrying out the task. The principle of efficiency outlined previously suggests that, other things being equal, we desire an algorithm that will deliver a referring expression that mentions as few attributes as possible: a minimal distinguishing description. From the point of view of computational complexity, the problem of constructing a **minimal distinguishing description** is equivalent to finding the minimal size set cover. In computational complexity theory, this problem is known to be NP-hard (Garey and Johnson, 1979), and any such algorithm is probably computationally impractical when entities have any more than a small number of properties that might be used in descriptions. Much of the work in providing algorithms for referring expression generation has therefore been concerned with finding heuristic workarounds that avoid these computational complexity issues.

There is insufficient space here to consider each of the algorithms in the literature in detail; however, to provide a flavor of what such algorithms contain, we show here the first of the fully specified algorithms to appear, as published in Dale (1992); this has served as a starting point for many of the subsequently proposed algorithms. The algorithm, which is essentially a variant of Johnson's greedy heuristic for minimal set cover (Johnson, 1974), is as follows:

Let L be the set of properties to be realized in our description; let P be the set of properties known to be true of our intended referent r, where a property is a combination of an attribute and a value for that attribute; and let C be the set of potential distractors as defined earlier. The initial conditions are thus as follows:
$C = \{\langle \text{all distractors} \rangle\}$;
$P = \{\langle \text{all properties true of } r \rangle\}$;
$L = \{\}$.

In order to describe the intended referent r with respect to the set C, we do the following:

1. Check Success:
   if $|C| = 0$ then return L as a distinguishing description
   elseif $P = \emptyset$ then **fail**
   else goto Step 2.
2. Choose Property:
   for each $p_i \in P$ do: $C_i \leftarrow C \cap \{x | p_i(x)\}$
   Chosen property is p_j, where C_j is the smallest set.
   goto Step 3.
3. Extend Description (with respect to the chosen p_j):
   $L \leftarrow L \cup \{p_j\}$; $C \leftarrow C_j$; $P \leftarrow P - \{p_j\}$
   goto Step 1.

To see how this works, suppose we have a context that contains the following entities with the properties indicated, and that the intended referent is e_1:

e_1: ⟨type, pen⟩, ⟨color, red⟩, ⟨brand, Staedtler⟩, ⟨size, large⟩
e_2: ⟨type, pen⟩, ⟨color, blue⟩, ⟨brand, Staedtler⟩, ⟨size, small⟩
e_3: ⟨type, pen⟩, ⟨color, red⟩, ⟨brand, Stabilo⟩, ⟨size, large⟩
e_4: ⟨type, pen⟩, ⟨color, green⟩, ⟨brand, Staedtler⟩, ⟨size, large⟩

Here, the property of being red rules out more distractors than does any other property possessed by e_1: it rules out both e_2 and e_4, whereas the brand and size attributes only rule out one distractor each, and the type attribute has no impact at all. We still then have to add additional information to rule out e_3: here, size does not help, but adding the brand does what is needed. On the other hand, if the intended referent was e_2, the color or size alone would be sufficient, and if the intended referent was e_3, the brand alone would be sufficient. Verifying that the algorithm does indeed provide these results is left as an exercise for the reader. In reality, since noun phrases always (or almost always) contain head nouns, the head noun indicating type is also incorporated into the resulting description, and for completeness the algorithm given here would have to be augmented to ensure this.

The algorithm here is intended to be quite general and domain independent; wherever we can characterize the problem in terms of the basic assumptions laid out earlier, this algorithm can be used to determine the content of context-dependent referring expressions. However, the algorithm also suffers from some limitations:

- As stated, it may satisfy the principles of adequacy and efficiency, but it does not pay heed to the principle of sensitivity: there is no guarantee that the properties selected will even be perceptible to the hearer. In the preceding scenario, for example, if the labels that indicate the brands of the pens are face down on the table, and the pens have no other brand-distinguishing characteristics, then the brand information is of no real value for the hearer.
- The algorithm only makes use of one-place predicates (such as the fact that our whiteboard pen is red), but as already noted, we can also make use of relational properties (such as the fact that the pen is on the table rather than on the floor) when describing entities.

Since this early algorithm was developed, a wide range of alternatives have been proposed, either to address these particular problems or to extend the coverage of the algorithms in other ways.

More Efficient Algorithms

Although the algorithm described here avoids the computational complexity of a literal interpretation of the principle of efficiency, it is still a relatively expensive way of computing a description. A second algorithm for referring expression generation that has had widespread influence is Dale and Reiter's (1995) incremental algorithm. This algorithm has three distinctive properties. First, the algorithm sacrifices the goal of finding a minimal distinguishing description in the interests of efficiency and tractability. It does this by considering the attributes that might be used in a description in a predefined order. This means that on occasion it may include a property with a discriminatory power that is made redundant by some subsequently incorporated property; however, Dale and Reiter argued that this is not necessarily a bad thing, since human-generated referring expressions also often contain informational redundancy (see, for example, Pechmann (1989)). It remains to be seen whether the algorithm provided by Dale and Reiter provides the same *kinds* of redundancies as those produced by humans.

Second, although the incremental algorithm contains a domain-independent, and therefore quite generally applicable, algorithm for building up the content of a referring expression, it does so by reference to a predefined list of properties, the content of which is dependent on the domain. This provides a convenient balance between generality and domain specificity. Third, when the algorithm considers whether a given property would be useful to include in a description, it carries out a check to determine whether the property in question is one that the hearer would be able to make use of in identifying the referent. In so doing, it also explicitly aims to address the principle of sensitivity. The incremental algorithm has served as the basis for a number of other algorithms in the literature.

Referring to Entities Using Relations

Another deficiency (noted previously) with respect to the greedy heuristic algorithm was that it could only make use of one-place predicates in determining which attributes of an entity to use in its description. The reason for this limitation is to avoid adding significant complexity to the algorithm: if we want to build referring expressions of the form *the red pen next to the coffee cup*, note that the entity to which we are relating the intended referent (in this example *the coffee cup*) is itself an entity for which we have to construct a referring expression. Once the generator decides that some other entity has to be introduced in order to identify the intended referent, a recursive call to the process of referring expression generation is required. There is clearly the scope here for an infinite regress, as in *the red pen next to the coffee cup next to the red pen next to the coffee cup next to* . . . . In informal terms, it would appear to be straight forward to deal with such cases appropriately, but capturing the required behavior algorithmically is a little more difficult.

As a solution, Dale and Haddock (1991) proposed an algorithm based on constraint satisfaction. This effectively builds up collections of properties for each of the entities to be described in parallel, and determines when the properties (or more precisely, the relations) used to describe one entity also support the identification of another entity. Krahmer *et al.* (2003) have proposed a solution based on viewing the domain of entities, properties, and relations as a labeled graph, with the problem of referring expression generation then being one of constructing an appropriate subgraph. This provides a very elegant solution to the problem, with well-understood mathematical properties.

Logical Extensions: Sets, Booleans, and Quantifiers

So far, we have pointed to algorithms that permit the use of both one-place predicates and relations in the construction of referring expressions. Although this provides for a wide range of possibilities, it still does not encompass all of the devices that humans use in constructing referring expressions. Notably, the algorithms discussed so far assume that the intended referent is a singular individual, and that it is to be picked out by the logical conjunction of the properties in the description. There are, of course, other possibilities here. We may sometimes need to refer to sets of entities (*Please pass me all the pens*), and it may sometimes be convenient to refer to entities not just in terms of conjunctions of properties, but also via other Boolean possibilities, such as the use of negation and disjunction. To return to our earlier example, it might in some circumstances be most appropriate for me to say *Please pass me the red pen that hasn't run out of ink*; and in cases in which we want to refer to a set of entities, there may be no property that is shared by all the intended referents, requiring an expression such

as *the red pen and the blue pen*. These ideas are explored in detail in van Deemter (2002), who presented generalizations and extensions of the incremental algorithm that cater to these possibilities. Creaney (2002) offered an algorithm that allows the incorporation of logical quantifiers, such as *all* and *some*, into descriptions.

Broader Issues and Outstanding Problems

In the foregoing discussions we have surveyed, albeit very briefly, the major aspects of referring expression generation that have been the focus of attention in the development of algorithms over the past 15 years. There are many other algorithms in the literature beyond those presented here, but the problems addressed are essentially the same. In this final section, we turn to aspects of the problem that have not yet received the same level of detailed exploration.

Other Forms of Anaphoric Reference

We have focused here on the construction of definite descriptions: references to entities that are in the common ground, either by virtue of their presence in the environment or because they have already been introduced into the discourse. Definite descriptions are not the only form of anaphoric reference: we can, of course, also use pronouns such as *it* and *one*-anaphoric expressions such as *the red one* to identify intended referents. Although the literature does contain some work on generating these forms of reference, they have not received the degree of attention that has been lavished on definite descriptions, and in particular there has been little work that has seriously attempted to integrate the various forms of reference in a unified algorithmic framework. Other forms of definite reference have also been neglected: in particular, there is no substantive work that explores the generation of associative anaphoric expressions, such as the use of a reference like *the cap* in a context in which the hearer can infer that this must be a first mention of the cap of a particular pen that is already salient in the discourse.

Initial Reference

An even more striking gap in the literature is any serious treatment of initial reference, as opposed to subsequent or anaphoric reference. Subsequent references to entities have a tendency to reuse information used in earlier references; so, for example, I might introduce an entity as *that Stabilo pen on the table* and subsequently refer to it as *the Stabilo pen*. The generation literature not only tends to ignore this influence of the initial form of reference on subsequent referring expressions, but is in general quite silent on the problem of how initial references can be constructed. There are a great many ways in which I might refer to a specific entity when introducing it into the discourse, and when we move beyond simple examples of collections of similar objects, as are often used in the literature, it becomes clear that the form of initial reference used has a lot to do with the purpose of the discourse and other aspects of the discourse context. Thus, my decision as to whether to introduce someone into the discourse as *a man I met at the bus stop*, or *a mountain climber I met last night*, or *an interesting guy I met*, will depend on what I have planned in terms of content for the rest of the discourse. The complexities of planning and reasoning required to explain how this selection process works are far beyond our current understanding.

The Pragmatics of Reference

Following on from the previous point, relatively little work has looked at the broader context of reference, and in particular the fact that, when we construct a referring expression, we may be doing many things simultaneously and attempting to achieve a variety of purposes. Building on the earlier explorations of Appelt (1985), the work of Kronfeld (1990) is a notable exception here, but we lack a worked-out computational theory of how reference functions within the wider context of language use, and, in particular, we have no formally well-specified explanations of the variety of purposes of reference. The bulk of the work in the field has focused on referring expressions as linguistic devices to distinguish intended referents from other entities in a given context, but this is a rather narrow and low-level view. We also use reference to maintain topic, to shift topic, to introduce contrasting entities, and to navigate a hearer's focus of attention in various ways, among a range of other higher level purposes. These are all relatively unanalyzed notions from a formal perspective, and the relationships between them need to be worked out more clearly before we can say that we have a proper computational theory of the use of reference and the part it plays in language. As is often the case, approaching this problem from the perspective of natural language generation may provide insights

that can also enrich our understanding of natural language analysis.

Generative Grammar

J Rooryck, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Like many linguistic terms, the phrase 'generative grammar' means different things to different practitioners of linguistics. The term 'grammar' itself can be loosely defined as the set of rules that accurately describe the combination of elements in a language. A properly 'generative' grammar is, roughly speaking, a grammar whose rules generate (i.e., produce) all and only the correct combinations of elements in a language. This definition corresponds to the use of generative grammar as a common noun. However, the term 'generative grammar' gradually received a much broader meaning as a proper noun, referring to the specific research program that is associated with the mentalist approach to language launched and developed by Noam Chomsky. In this article, the basic characteristics of both meanings of generative grammar are sketched, and the relationship between them is elucidated.

The narrower, common noun meaning of the term 'generative grammar' originates in mathematical recursive function theory and is also used in computer science. A generative grammar, then, is one of two types of formal grammars, generative and analytic. Such a formal grammar comprises a set of rules, which in turn define a possibly infinite set of finite strings composed of a set of fixed elements. These elements need not be words of natural language; they may be any kind of symbol.

A classical generative grammar contains four components: (1) a finite set of nonterminal symbols, (2) a start symbol contained in the set of nonterminal symbols, (3) a finite set of terminal symbols, and (4) a finite set of production rules that rewrite a (string containing at least one) nonterminal symbol into a string of terminal and/or nonterminal symbols. Rules

that can also enrich our understanding of natural language analysis.

Generative Grammar

J Rooryck, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Like many linguistic terms, the phrase 'generative grammar' means different things to different practitioners of linguistics. The term 'grammar' itself can be loosely defined as the set of rules that accurately describe the combination of elements in a language. A properly 'generative' grammar is, roughly speaking, a grammar whose rules generate (i.e., produce) all and only the correct combinations of elements in a language. This definition corresponds to the use of generative grammar as a common noun. However, the term 'generative grammar' gradually received a much broader meaning as a proper noun, referring to the specific research program that is associated with the mentalist approach to language launched and developed by Noam Chomsky. In this article, the basic characteristics of both meanings of generative grammar are sketched, and the relationship between them is elucidated.

The narrower, common noun meaning of the term 'generative grammar' originates in mathematical recursive function theory and is also used in computer science. A generative grammar, then, is one of two types of formal grammars, generative and analytic. Such a formal grammar comprises a set of rules, which in turn define a possibly infinite set of finite strings composed of a set of fixed elements. These elements need not be words of natural language; they may be any kind of symbol.

A classical generative grammar contains four components: (1) a finite set of nonterminal symbols, (2) a start symbol contained in the set of nonterminal symbols, (3) a finite set of terminal symbols, and (4) a finite set of production rules that rewrite a (string containing at least one) nonterminal symbol into a string of terminal and/or nonterminal symbols. Rules

apply in any order and any number of times until all nonterminal symbols are rewritten as strings of terminal symbols. The set of strings with terminal symbols that can be generated this way is called the 'language' generated by the grammar. Generative grammars can be classified into four types conforming to the so-called Chomsky hierarchy. These types differ by an increasingly stricter format for production rules and concomitantly fewer formal languages. In this formal sense, the term 'grammar' is therefore used only by analogy with the term 'grammar' in natural languages.

Take a generative grammar that consists of the set of nonterminal symbols {X,Y} with X the start symbol, the set of terminal symbols {a,b}, and the rules X → aYb, Y → Xb, and Y → ba. The arrow inside the rules carries the instruction 'is rewritten as.' Applying X → aYb, followed by an application of Y → Xb yields the intermediate string a**Xb**b. This string still contains a nonterminal symbol. Therefore, it requires reapplication of the rule X → aYb (yielding a**aYb**bb) and subsequently the rule Y → ba to yield a string that consists solely of terminal symbols, in this case aa**ba**bbb. This grammar also generates other strings (infinitely many, in fact), which together constitute the language of this particular generative grammar.

This formal apparatus provides a powerful tool for analyzing natural language. The set of terminal symbols, then, contains the vocabulary of a natural language, say, English. The set of nonterminal symbols contains word class labels (noun, verb, etc.), as well as larger syntactic units, such as noun phrases and sentences. The largest syntactic unit, the sentence, can be taken as the nonterminal start symbol. The production rules of a descriptively adequate grammar generate the set of sentences that an English speaker would understand as uniquely English, and they fail to generate sentences and phrases that are not judged to be proper English by such a speaker. An English speaker will readily accept *the red book* as a grammatical unit, but not **the book red*. A more traditional description would then state that in English, adjectives end up in front of nouns and do not appear after them. In a generative grammar of English, this descriptive fact is a result of the order specified in the rewriting rule. In this rule, a noun phrase (NP) is rewritten as a string in which the Determiner (Det) is followed by the adjectival phrase (AP) and the noun (N) in that order: NP → Det AP N. Replacing the nonterminal symbols Det, AP, and N by *the*, *red*, and *book* respectively yields *the red book*. By contrast, the rewriting rule that makes adjectives end up after nouns (NP → Det N AP) is not part of the generative grammar of English. The grammar thus provides a fully explicit syntax of English, rather than the informal or implicit characterization often found in traditional grammars. English speakers have rules that allow them to generate an infinite number of new sentences by using a finite vocabulary, and to interpret entirely new combinations of words. A generative grammar can be recursive: the output of one application of a rewrite rule can serve as the input for a later application of the same rule. This mechanism of recursion is also active in natural language; it is responsible for such sequences as *the sister of the brother of the grandfather of the niece of an acquaintance of my aunt*, which can in principle be infinitely extended by recursion, limited only by performance factors.

Applying this line of thinking in a mentalist context, Noam Chomsky in the late 1950s revolutionized the way of looking at natural language. The study of language could reveal "abstract principles that govern its structure and use, principles that are universal by biological necessity and not mere historical accident, that derive from the mental characteristics of the species" (Chomsky, 1975: 3). The computationally 'generative' properties of the grammars of natural languages, and more in particular the property of recursion, is one instance of such abstract, universal, biologically necessary characteristics of the grammars developed by the human species. It should be noted, however, that it is perfectly possible to study properties of formal generative grammars outside of the mentalist context, i.e., generative grammars can be part of nonmentalist approaches to grammar.

Nevertheless, the school of thought on the mentalist nature of language developed by Chomsky and his followers came to be known – rather misleadingly and somewhat erroneously – under the popular name 'generative grammar' or 'generative linguistics,' this time used as a proper noun. In this much broader meaning, the name should be taken as no more than an expedient, historically motivated *pars pro toto*, encompassing not only syntax but a mentalist model of grammar also comprising phonology, morphology, and semantics. Accordingly, this school of thought is not limited to finding the generative grammar generating all and only the grammatical sentences of a language in the formal sense defined earlier in this article. Perhaps even more surprisingly, however, the model of generative grammar (as a proper noun) developed in the Minimalist program does not even contain a generative grammar in the common noun sense. Rewriting rules have been entirely dispensed

with in favor of more elementary, structure-building operations. Thus, the proper noun meaning of 'generative grammar' has entirely outgrown the common noun meaning. Understandably, then, Chomsky himself opposes the use of 'generative grammar' to describe his approach to language, preferring terms such as the rather laborious 'principles and parameters framework' or the succinctly elegant 'biolinguistics.' Despite such opposition, the term is in widespread use as representing the scientific paradigm that has dominated theoretical linguistics for the past 50 years. The remainder of this article is therefore devoted to characterizing generative grammar as a proper noun in the sense already defined.

The approach to language initiated by Chomsky is radically *internalist*. Language is viewed as a species-specific property, part of the mind/brain. The object of study of linguistics as a part of cognitive science is this mental faculty for language. Chomsky radically equates linguistic theory with the study of *I(nternal)-language,* language as an internal cognitive structure. A theory of grammar is a model of the speaker's linguistic competence, part of the internal structure of his mind. A speaker of a language has internalized a system of rules relating sound to meaning in a particular way. The task of the theoretical linguist is to describe and explain the linguistic competence of a native speaker, the linguistic knowledge of language present in the minds of individuals. A linguist construes hypotheses concerning this internalized system. *E(xternal)-language* is not part of the theory of language and comprises sundry approaches to language as it is used in society, literature, or communication.

The fact that any child can acquire any of the 6000 or so languages in the world in a relatively short period of time and under imperfect input conditions gives rise to the *Innateness Hypothesis*. This hypothesis encapsulates the claim that some set of fundamental characteristics of all human languages must be the same, and part of the *Language Faculty.* The faculty of language is part of the human biological endowment. Children are born with a faculty of language in its Initial State, i.e., the state of the faculty of language before it is exposed to the input of a particular language. This innate knowledge is sometimes called *Universal Grammar.* Language acquisition requires interaction with the environment, in the same way birds need interaction with the environment to 'learn' how to fly or sing. It is assumed that particular properties of Universal Grammar are parametrized, hence the term Principles and Parameters framework. Particular choices for each parameter of UG lead to specific grammars of individual languages. The Initial State is therefore progressively replaced during acquisition with grammars that come to resemble the Steady State, i.e., the internalized grammar of the language of a given adult speaker.

phonetic distance and allow a formal study of natural classes in which the plausibility of a rule is reflected in the relative simplicity of its statement. Concern for simplicity and formal statement became a cornerstone of the generative approach.

Chomsky and Halle's landmark study *Sound Pattern of English* (1968) (SPE) is the first systematic exposition of generative phonology. A key feature was to take seriously the notation in terms of which sounds are represented and rules are formulated. SPE's analysis of the English Vowel Shift and Velar Softening illustrate these points well. Alternations among [aj] ≈ [i] (*divine*, *divin-ity*), [ij] ≈ [e] (*serene*, *seren-ity*), and [ej] ≈ [æ] (*profane*, *profan-ity*) pervade English vocabulary. Because the short vowels of *rig**i**d*, *perpet**u**-al*, and *fin**a**l* (cf. *rigid-ity*, *perpetuity*, *final-ity*) are stable, the long vowel must underlie the [aj] ≈ [i], [ij] ≈ [e], [ej] ≈ [æ] alternations. But the underlying quality of the vowel is reflected in the short variant. Hence, SPE posits underlying /i:/, /e:/, and /æ:/ and two ordered rules. The first rule shortens the vowel before certain suffixes. Any remaining long vowels are diphthongized and then rotate their nuclei by two rules: the first interchanges high and mid /i/ and /e/ by changing [αhigh] to [−αhigh]; the second interchanges mid (derived from high by the first change) and low vowels by changing [αlow] to [−αlow]. Thus, in the derivation of *divine* the high vowel switches places with the mid vowel of *serene* and then with the low vowel of *profane* (**Figure 2**).

This vowel interchange defined a new category of sound change, and SPE devoted a chapter to its documentation in the historical development of English. Although stunning in itself, the analysis of the Vowel Shift allowed linguists to make sense of a variety of consonantal changes as well. For example, /k/ is replaced by /s/ before suffixes beginning with /i/: *critic*, *critic-ism*; *medic*, *medic-ine*. But the trigger in *critic-ise* is a back vowel [aj] at the phonetic surface. However, if Velar Softening applies before Vowel Shift (to /kritik-i:z/), then the latter is not exceptional at all. On the strength of such analytic insights resting on a formally explicit methodology, SPE was universally regarded as a tremendous theoretical and descriptive advance.

/devi:n/	/sere:n/	/profæ:n/	Phonological representation
ij	ej	æj	Diphthongization
ej	ij	—	[αhigh] → [-αhigh]
æj	—	ej	[αlow] → [-αlow]

Figure 2 Derivations of *divine*, *serene*, and *profane*.

The generative methodology in which systematic alternations are derived from a common underlying form by an ordered set of rules was successfully applied to such well-known languages as Russian, Japanese, French, and Spanish by Chomsky and Halle's first generation of graduate students. A critical mass of detailed analyses from the generative perspective accumulated that uncovered numerous problems and research questions – many of them still unresolved. We mention four here.

Paul Kiparsky (1968, 1971) pointed to the excessive abstractness of many analyses adhering to the generative method, raising the question of how a learner could arrive at such rules and representations in the absence of knowledge of their historical antecedents. He suggested that abstract representations are motivated by alternations and that grammars change to states in which the underlying representations can be induced by rules that state generalizations over the surface phonetic representation.

Charles Kisseberth (1970) called attention to various rules in the phonology of Yawelmani that conspire to ensure that the output does not contain three successive consonants. The language lacks roots of this structure; and when stems and suffixes are combined to create CC + C or C + CC sequences, various rules come into play that either delete one of the consonants or insert a vowel. Moreover, another rule elides a vowel in the context VC__CV; it can be understood as a more general V → Ø process that is blocked just in case its output would violate *CCC. With its emphasis on formal connections among rules, the SPE model was unable to express the functional unity among these diverse processes. More generally, it was unclear how to formalize the notion of rules applying or blocking to satisfy a constraint.

David Stampe (1979) emphasized the importance of substantive rather than formal considerations in shaping phonological structure. He tried to make sense of two puzzles in acquisition. Languages such as Catalan, Russian, and German have a process devoicing word-final obstruents. Acquisition studies fail to detect a stage in which the child pronounces final [b, d, g], reflecting incomplete mastery of the rule. Rather, child speech conforms to the process from the outset. More significantly, child language is rife with sound changes that lack any precedent in the mature grammar. The sound substitutions of child phonology are thus hard to understand as immature versions of the rules of adult grammar. According to Stampe, they reflect a set of innate processes that are curtailed in the process of language acquisition so that the child's output matches the ambient language. Stampe also drew a sharp distinction between such natural processes and more phonetically arbitrary

rules such as SPE's Vowel Shift and Velar Softening that state generalizations over limited sets of lexically related words. In his view, phonological processes are what the child brings to the language, whereas phonological rules are what the language's vocabulary brings to the child.

Finally, with its emphasis on rules of sound change, the SPE model has little to say about phonotactics – static constraints on word shape that are unsuited to rules of sound change and seem best treated as conditions on representation that outputs must respect. Kenstowicz and Kisseberth (1976) called attention to the problem that constraints on lexical shape are often duplicated by rules of sound change that can be thought of as bringing the representation in line with the constraint. This point of view was explored by Sommerstein (1974).

Enriched Representations: 1975–1990

The SPE model has a simple representational format: An utterance is a string of feature matrixes punctuated by boundary symbols of various kinds to indicate stem, morpheme, word, and phrase junctures. Rules changing feature structure in a local context are ill suited to the phonology of tone, stress, and length. These suprasegmentals became the object of intensive scrutiny that had a profound effect on how all sounds are represented and manipulated by the rules of grammar.

The tonal languages of Africa proved particularly perplexing. Although phonetically expressed as a vocalic feature, a tone's phonological behavior is largely autonomous from the segmental string. For example, in Mende lexical items belong to a limited number of tonal melodies such as high (*kɔ́* 'war,' *pélé* 'house,' *háwámá* 'waist') or falling (*mbû* 'owl,' *ngílà* 'dog,' *félàmà* 'junction'). The problem is to express the generalization that the falling tone is restricted to monosyllables and breaks into H + L under suffixation (cf. *mbú-mà* 'on owl'). If tone is a segmental feature analogous to [labial] or [nasal], then complicated rules are required to transform [+fall] to [+hi] followed by [−hi]. Also, in tonal languages, when a vowel elides the associated tone typically shifts to an adjacent syllable (cf. Margi (Marghi Central) *kúm-árì* 'meat (DEF)' and *wù* 'tree,' *wǎ̀rì* 'tree (DEF)' from /wù-árì/.

Building on the work of Wil Leben, Edwin Williams, and others, John Goldsmith (1976) made a significant breakthrough on this problem by proposing that tonal features be represented on a separate level (tier) associated with, but autonomous from, the segmental tier. Conditions governing a well-formed association of tones and vowels such as one-to-one, left-to-right mapping and no unassociated tones or vowels derive the surface patterns via simple rules operating in local environments (Figure 3A–B). And if tones are autonomous then vowels can delete while a tone persists on its own tier and maps to an adjacent syllable to ensure maximal association (Figure 3C).

Stress poses similar locality questions. For example, English words with final primary stress such as *T'enness'ee* invert their Weak-Strong contour when followed by a stronger stress: *T'ennessˈee W''altz*. If stress is represented as a feature, the final syllable must be demoted in value ([1stress] → [2stress]), while the first is raised ([2stress] → [1stress]). One never finds [nasal] or [back] exhibiting such long-distance complementary changes. Mark Liberman (1975) and Liberman and Prince (1977) made another conceptual advance by seeing stress as the reflection of an abstract property of prominence formalized in terms of a metrical grid in which each syllable is associated with a column of marks indicating its relative prominence in the word or phrase. With this notation, the inversion can be described by a simple rule that slides the top element of the weaker of the two clashing stresses to the next available landing site – the first syllable – to create a rhythmically more balanced contour in which two stronger stresses are separated by a weaker one (Figure 4).

Finally, although the 'syllable' was mentioned throughout the analysis of English in SPE, the notion had no formal status in the theory. Various researchers proposed that syllables could be represented by boundary symbols analogous to word junctures in

Figure 3 Autosegmental mapping of tones.

Figure 4 Grid notation for stress inversion.

Table 1 Arabic morphology

/d-r-s/		/ħ–m-l/	
daras-a	'he studied'	ħamal-a	'he carried'

devr-i	devir	devir-den	'transfer'

order to express the frequent conjunction of preconsonantal and word-final position. Adapting insights of Kenneth Pike and Jerzy Kuryłowicz, Elizabeth Selkirk (1982) proposed that the syllable is a constituent with internal structure of onset and rhyme that organizes the individual phonemes. With the syllable given official grammatical status, rules of vocalic epenthesis (Selkirk, 1981) and consonantal deletion (Steriade, 1982) can be formalized as methods to achieve a parsing of segments in accord with limitations on syllable shape, such as the traditional sonority hierarchy.

The ideas that features appear on autosegmental tiers and that an invisible hierarchical structure underlies words and phrases proved especially fruitful. Much of the generative research of the next 15 years involved extending and exploring the consequences of these proposals. We mention a few highlights.

Bruce Hayes (1980, 1985) analyzed the stress contours from a variety of languages with rules that group syllables into iambic (weak-strong) and trochaic (strong-weak) metrical feet in a left-to-right or right-to-left sweep of the word. Metrical stress research suggested that for restricted areas of phonology Chomsky's Principles and Parameters methodology was appropriate. Other influential studies of metrical stress include Prince (1983), Halle and Vergnaud (1987), and Dresher and Kaye (1990).

The notion of phonological features on separate tiers was extended to a variety of problems. John McCarthy (1979) suggested that the notorious root and pattern morphology of Semitic languages such as Arabic could be formalized analogous to the behavior of tones. As illustrated in Table 1, derivational relations among words are marked by changes in syllabic structure rather than overt affixation: perfects have the shape CVCVC, nominals CVCC, and agentives CVCCVVC. If the radical consonants [drs] 'study' and [ħml] 'carry' are represented on an autosegmental tier, then the same principles that control tonal structure (left-to-right association and multiple linking) can describe the structure of these words. Biradicals such as [md] 'stretch' seem to spread their second consonants to fill out a CVCVC template (cf. *madadna* 'we stretched') comparable to the extension of the L tone in the HL melody of Mende *félàmà*.

Clements and Keyser (1983) proposed extending the CV representation to all languages so that a greater variety of phonological processes could be expressed in autosegmental terms. For example, long consonants and vowels can be represented as one feature matrix associated with two adjacent CV positions. With this notation, changes in quantity involve the addition or deletion of CV slots. Their study demonstrated how the disparate changes of vowel shortening, consonant degemination, and vowel epenthesis illustrated by the Turkish data in Table 2 can be formalized as by-products of the organization of segments into CVC syllables (Figure 5).

The CV tier and, in particular, the possibility of empty skeletal positions intervening between phonetically adjacent segments was investigated in considerable detail by researchers working under the banner of Government Phonology (see Kaye *et al.*, 1990). For example, whereas the SPE model would posit a rule deleting the medial schwa to account for the V ≈ Ø alternation in French *revenir* [rɛvnir] 'to come back' (cf. *revienne* 3 SG. PRES. SUBJUNCTIVE), Government Phonology postulates an empty nucleus [revønir] (Charette, 1990). This approach minimizes the role of rules in favor of constraints on representations – in particular, the distribution of empty elements. The problem was conceived of as parallel to the distribution of empty syntactic elements (traces) in which Chomsky's (1981) notion of proper government was adapted to phonology. More generally, phonological expressions are viewed as sequences of C and V elements organized by syntactic principles based on the concept of government couched within an overarching Principles and Parameters methodology.

Building on observations by Joan Mascaró and K. P. Mohanan, George N. Clements (1985) proposed that features are organized into a hierarchical tree structure, such as in Figure 6. This notation allows formal expression of the observation that certain features introduce subdistinctions within the class of other features rather than partitioning the entire set of speech sounds into two groups of comparable status such as [±consonantal]. For example, the feature [anterior] is only relevant for coronal consonants. More important, the feature tree allows one to formalize the observation of recurrent feature sets

Figure 5 Autosegmental mapping of Turkish data.

Figure 6 Hierarchical tree structure for features.

in assimilation rules in which, typically, all the subsidiary place features are spread as well.

Also, some sound changes can be treated as deletion and insertion of nodes in the feature tree, for example, debuccalization of $s \rightarrow h$ as the removal of the supraglottal place node, leaving the laryngeal articulator to implement [continuant].

Several other lines of research were inspired by autosegmental-metrical structure. Pierrehumbert (1980) demonstrated that the intonation contours of English can be analyzed as sequences of tones analogous to the melodies found in African languages such as Mende. For example, the rising interrogative contour is composed of a L* pitch accent on the major stressed syllable and a H% boundary tone realized at the end of the intonational phrase. Selkirk (1980, 1986) extended the prosodic hierarchy to include phonological words and phrases so that the domains of sentence-level phonological processes could be defined and studied. McCarthy and Prince (1986/1996) opened up the study of truncatory phenomena such as hypocoristics and reduplication to formal scrutiny. Their Prosodic Morphology hypothesis stated that the templates underlying such structures are not arbitrary sequences of CV slots but rather prosodic categories such as light and heavy syllables and metrical feet whose precise characterization should correspond to how these units function elsewhere in the language. For example, the truncation *Elizabeth* → *Liz* minimizes the base while respecting the requirements on a freestanding English word – a bimoraic foot. Mokilese prefixal reduplication, seen in *pok-poki* 'beat,' *paa-pa* 'weave,' and *koo-kookɔ* 'grind coconut,' converges on a heavy syllable (CVC, CVV), whereas in Diyari (Dieri) the CV(C)CV reduplication template underlying *kanku-kanku* 'boy' and *kulku-kulkuŋa* 'jump,' *tjilpa-tjilparku* 'bird (species)' consists of a disyllabic trochaic foot.

Starting with Baudouin de Courtenay in the 19th century, linguists had the impression that phonological rules fall into two broad classes that are exemplified by the English Velar Softening of *electric* ≈ *electric-ity* vs. the flapping of *write* ≈ *wri-writer*. Rules of the first type have exceptions, substitute contrastive segments, and typically apply at the juncture between morphemes. Rules such as flapping tend to be automatic, may introduce allophones, and may apply morpheme internally (cf. *a*[ɾ]*om* vs. *a*[t^{h}]*omic*). In a pair of influential papers, Paul Kiparsky (1982, 1985) developed a Lexical Phonology model of the grammar that formalized this intuition in an especially perspicuous way. Rules of the first type (lexical rules) are placed inside the lexicon and integrated with the morphology to apply after each rule of affixation. As such, lexical rules are inherently cyclic. Adapting Chomsky's notion of the 'strict cycle,' Kiparsky offered an explanation for why lexical rules normally fail to apply morpheme internally in contrast to postlexical rules, which typically introduce allophones regardless of context. Although this approach was initially attractive, problems arose in extending this model to other languages, necessitating complex distinctions among affixes (level-1 vs. level-2). Also the tight connection between morphological and phonological domains on which the model is based is challenged by bracketing mismatches, such as *ungrammaticality* in which the morphology demands the parse [*un*+*grammatical*] + *ity* but the phonology requires *un*+[*grammatical* + *ity*].

Constraint-Based Models: 1990–2005

As more languages were analyzed from the autosegmental and metrical perspectives, recurrent cross-linguistic patterns were discovered, suggesting that a higher level of explanatory adequacy was within reach. The tension between descriptive coverage and theoretical economy came to a head with some

linguists defending the latter at the cost of more elaborate representations and derivations (Jonathan Kaye's 1990 Government Phonology) and others looking to connectionist-inspired modeling of 'soft' universals (John Goldsmith's 1993 Harmonic Phonology) or competing principles that evaluate representations (Luigi Burzio's 1994 analysis of English metrical structure).

Prince and Smolensky (1993) addressed these concerns as well as the unresolved problems from the 1970s with a new model of phonological derivation (Optimality Theory, OT) in which rules are abandoned and the explanatory burden is placed entirely on universal grammar (UG) constraints. Plausible descriptive coverage is ensured by the idea that constraints conflict (echoing Stampe) and that the conflict can be resolved by a strict ranking or prioritization. OT makes it possible to formally express Kisseberth's intuition that inputs are mapped to outputs in order to satisfy a particular objective. And with its basic distinction between faithfulness and markedness constraints, OT formalizes Stampe's intuition that the radical simplifications of child speech reflect innate phonetic biases that must be overcome so that the resultant adult grammar is the residue of these biases. Finally, given that OT constraints shape the output rather than the input, Kenstowicz and Kisseberth's duplication problem is resolved. Most important, the OT model passes the basic test of pairing input with output in an explicit and workable fashion. For these reasons, OT quickly captured the attention of the generative school whose research agenda largely focused on an exploration of its implications for analysis and theory.

The OT model consists of two basic functions. GEN constructs a large (possibly infinite) pool of candidate outputs for any given input, which are then EVALuated by a fixed UG set of conflicting constraints (CON) that sift through the pool of candidates to eliminate all but the correct output. Grammars differ in the ranking of the constraints, which is the major learning task in acquisition. We illustrate with the crosslinguistic treatment of word-final rising sonority clusters, for example, in the stem of *theatr-ic*. English *théa*[tər] inserts a schwa, Canadian French *théâ*[t] deletes the liquid, while European French *théâ*[tr] remains faithful to the input. The relevant constraints appear in (1) and their evaluation of these candidates appears in Table 3.

(1) Max-C: Do not delete a consonant.
Dep-V: Do not insert a vowel.
Sonority Sequencing (Son Seq): A sonority peak is a syllable peak.

The grammar of English imposes the ranking Son Seq, Max-C >> Dep-V so that the faithful candidate *thea*[tr] and the truncating *thea*[t] are penalized in comparison to the winning candidate with epenthesis *thea*[tər]. These evaluations are summarized in Table 4. Canadian French (*théâ*[t]) demotes the ban on truncation (Son Seq, Dep-V >> Max-C), whereas European French (*théâ*[tr]) demotes the ban on nonsyllabic sonority peaks (Dep-V, Max-C >> Son Seq).

During its initial phase, OT concentrated on recasting the basic insights of prosodic and autosegmental phonology. This research also uncovered cases of top-down and other remote effects (Berber syllabification, Hindi stress, and Malay reduplication), which are handled effortlessly by OT constraints defined over fully formed output structures but which require phonological rules to look ahead of themselves (a formal impossibility in the serial model of SPE). Other achievements include a much more nuanced and elaborated understanding of markedness (structural complexity) that has resulted in typologies with rich implicational hierarchies. The OT model also provides a useful framework for studying phonological development from an initial state in which markedness constraints dominate faithfulness constraints and has fostered the study of learning algorithms (Tesar and Smolensky, 1998).

Because the OT architecture involves a one-step mapping from input to output, it is immediately confronted by the pervasive serialism (e.g., *writer vs. rider or writer-rider*) on which the original SPE model is predicated. OT has chipped away at this problem. Some cases have been attributed to faithfulness to other members of a stem's paradigm. Other researchers have proposed intermediate stages in the input–output mapping that mirror Lexical Phonology's stem and word levels. However, a nagging and

thea[tr]		*!	

sizable residue of examples, such as Canadian English *title* [tʰʌjɹəl] (cf. *tidal* [tʰaːjɹəl]), persists as an outstanding problem (Idsardi, 1998).

Current Trends

Constraint-based formalisms have opened up a wider range of factors that can be taken into account to model recurrent sound patterns. A lively debate has arisen over the phonetic grounding of phonological structure and, more generally, the relation between phonetics and phonology. Traditionally, phonology is held to deal with categorical (symbolic) distinctions and phonetics with continuous movements of articulators and associated acoustic effects. But research in the 1980s revealed systematic gradient differences among languages that provoke the question whether phonology should expand to encompass the gradient or whether the grammar includes a distinct phonetic component.

Another trend extends the data and methods for studying phonological competence. Traditionally, phonologists have concentrated on the study of systematic generalizations in a language's inherited lexical stock with an occasional bow to supporting evidence from language games, loanwords, and speech errors. Under the banner of Laboratory Phonology (Pierrehumbert *et al.*, 1996), linguists are adopting more experimental approaches in which subjects are tasked with learning artificial languages, judging similarity between carefully controlled stimuli, and producing tongue twisters. Computer-accessible databases have made it possible to study a language's lexicon in an efficient and accurate manner. Generative phonologists are turning their attention to topics that were understudied or ignored in the classical period. We mention three here.

With its concentration on rules, generative phonology abstracted away from questions of frequency – as long as an alternation or phonotactic restriction was regular it was assumed to be part of the speaker's competence. Recent research suggests that speakers have knowledge of frequency patterns in the lexicon. For example, Dutch has final devoicing. Ernestus and Baayen (2003) showed that there are significant differences in the number of voiced versus voiceless obstruents that underlie the alternation (e.g., final [p] derives from underlying /p/ for 97% of the lexicon and from /b/ for just 3%; final [x] derives from underlying /x/ for 19% of the lexicon and from voiced /ɣ/ for 81%. When Dutch subjects were asked to supply the inflected form of a pseudo stem, their responses mirrored the lexical frequencies.

Anttila (2002) studied the competition between Finnish rules that shift stem-final [a] to [o] before the suffix [i] (/kana-i-ssa/ > *kanoissa* 'hen') versus deletion in the same context (/muna-i-ssa/-> *munissa* 'egg.' Although neither rule applies categorically, there are clear statistical differences as a function of the preceding consonant and stem vowel. The change to [o] is preferred to deletion according to the following hierarchies: stem vowel /i/ > /a, e, u/ > /o/, preceding consonant velar > dental > labial. Anttila modeled this orderly variability with competing OT grammars that differ in the ranking of constraints penalizing sequences of similar sounds.

The notion of contrast has been resuscitated and addressed directly in several lines of research. Flemming (2005) argued that the relative markedness of a phoneme can only be judged in relation to other segments in the system. For example, he observed that, in languages contrasting front and back vowels, front rounded /y/ and back unrounded /ɯ/ are only added to the phonemic inventory after the more peripheral vowels /i/ and /u/ are chosen. But in vertical vowel systems that do not contrast front and back, the central vowel /ɨ/ is the optimal high vowel. Recasting some of Bjorn Lindblom's ideas on vowel dispersion, Flemming modeled a vowel inventory in terms of competing constraints that balance articulatory effort with maximizing the number of contrasts along a phonetic dimension and maintaining sufficient phonetic distance between pairs of elements. Thus, if a language makes no contrast in the F2 dimension, then minimizing articulatory effort will favor the central vowel /ɨ/. But if a contrast is introduced, then the peripheral vowels /i/ and /u/ will be chosen first on the grounds of phonetic distance. More vowels such as /y/ or /ɯ/ are added at the cost of decreasing the phonetic difference between contrasting pairs.

Padgett (2003) discussed the role of contrast in motivating and restricting the scope of a Russian sound change that fronts unrounded /ɯ/ to /i/ after velars. The *ɯ* → *i* change did not occur after labials or dentals because these consonants are palatalized before /i/; fronting after /p/ would replace a more widely spaced /pʲi/ versus /pɯ/ contrast with the auditorially less optimal /pʲi/ versus /pi/. The fronting of /ɯ/ occurs after velars because an earlier sound change shifted /ki/ to /tʃi/ and so the hard-soft consonantal contrast is realized as a more perceptible dorsal-coronal one.

Based on a typological survey of contrasts in aspiration, Steriade (to appear) discerned an implicational hierarchy of contexts in which a /t/ versus /tʰ/ opposition is neutralized: preobstruent > word-final > presonorant > prevocalic. The hierarchy does not align with syllable onset versus coda position but rather with the contexts in which the principal acoustic cue (voice onset timing, VOT) to aspiration is

optimally realized. A general Licensing by Cue format is envisioned in which phonetic perceptibility scales project corresponding ranked constraints into the OT grammar.

Blevins (2004) defended a more traditional view that synchronic grammars compute over representations in which phonetics is only reflected obliquely via distinctive features in their classificatory function. The rich phonetic grounding uncovered by studies such as Steriade's is attributed to asymmetries in actual speech samples that form the basis for the induction of the grammar by the child, who may misinterpret *anpa* as *ampa*, rephonologize a speaker's [ʔa] < /a/ as /ʔa/, or ground a phonological analysis in a different exemplar in a phoneme's range of permissible variants. This point of view places the study of sound change on an equal footing with synchronic structure and seriously implicates language acquisition as well. It encourages generative phonologists to adopt a new, more integrative approach in their research program. But, despite changes in emphasis and technique, generative phonology remains committed to an explicit modeling of linguistic competence.

This article is reproduced from the previous edition article by James D McCawley, volume 3, pp. 1398–1403, (c) 1994, Elsevier Ltd., with a foreword by Randy Harris.

Foreword (by Randy Harris)

There is little that can or should be added to the definitive epitome of generative semantics you are about to read, by James D. McCawley (1938–1999), except (1) a few words about the importance of McCawley to the movement, which is perhaps, less prominent in an article of his own authorship than it may have been from anyone else's pen, and (2) a few additional citations.

Each of the four main figures McCawley associates with generative semantics – George Lakoff (b. 1941), John Robert (Háj) Ross (b. 1938), Paul Postal (b. 1936), and himself – contributed very substantial elements to its identity, but McCawley embodied the approach, from his feet to his very lively eyebrows, and especially above. He was, in all senses of the phrase, its presiding genius. He helped bring it to life in lengthy, rollicking, mid-1960s telephone calls with Lakoff between Cambridge, Massachusetts, and Chicago. He supplied what many regarded as its strongest arguments and its most compelling analyses, some of which brought Postal into the program. He spent his entire career in the movement's epicenter, the University of Chicago. He continued to publish comprehensive works in the generative semantics spirit long after the label had fallen into disrepute, especially *Syntactic Phenomena* (1993a) and *Everything That Linguists Have Always Wanted to Know about Logic* (1993b). He believed in generative semantics to the very end, not in all of its specific proposals (relentlessly honest, he cheerfully and publicly dropped analyses that no longer fit his evolving views and cheerfully welcomed views that did, no matter what their origin), and certainly not in the label itself (indeed, he renounced all theoretical labels), but in its substance.

Further reading in generative semantics include Lakoff (1971), McCawley (1976, 1979), Postal (1972), Ross (1972, 1973), Newmeyer (1980, McCawley cites the 1986 second edition; the 1980 first edition has more on generative semantics), Lakoff (1989), Harris (1993a, 1993b), Huck and Goldsmith (1996), and McCawley (1981). Also of note are the two festschrifts for McCawley: Brentari *et al.* (1992) and Zwicky *et al.* (1970/1992).

Generative Semantics (by James D McCawley)

The term 'generative semantics' (GS) is an informal designation for the school of syntactic and semantic research that was prominent from the late 1960s through the mid-1970s and whose best-known practitioners were George Lakoff, James D. McCawley, Paul M. Postal, and John Robert Ross.

GS Positions on Controversial Issues

The name GS gives undue prominence to one of many issues on which GS-ists took positions that conflicted with those of more orthodox generative grammarians, an issue that in hindsight seems arcane because it is intelligible only against the background of the once widely accepted assumption (shared then by GS-ists and their adversaries) that there must be a single level of linguistic structure for which it is appropriate to give a system of 'generative rules' (i.e., rules giving a complete specification of what structures are well-formed on that level) and to which all other levels of structure are related by 'interpretive rules.' The issue commemorated in the name GS was that of whether the privileged level was semantic structure (the GS position) or was a level of syntactic structure as distinct from semantic structure (the position of Chomsky and other 'interpretive semanticists'). The prominence that has been given to that arcane issue should not obscure the fact that GS-ists disagreed with other generative grammarians on many far more substantial issues, such as the following:

a. Whether sentences were 'grammatical' or 'ungrammatical' in themselves rather than relative to (linguistic and extralinguistic) contexts and to possible interpretations. GS-ists rejected the then popular idea that a language can be identified with a set of sentences and took syntactic derivations as implying that the surface form in question was grammatical not absolutely but only relative to the meaning represented in its deep structure and to any contextual factors to which steps in the derivation are sensitive.
b. The nature of semantic structure. GS-ists held that semantic structures have the same formal nature as syntactic structures, except for having semantic rather than morphological entities as their ultimate constituents, while interpretive semanticists either were reluctant to make any concrete claims about the nature of semantic structure (e.g., Chomsky, 1972: 137) or adopted a conception of semantic structure that differed considerably in formal nature from syntactic structure (e.g., Jackendoff, 1972).
c. The nature of syntactic categories. Much work in GS attempted to reduce syntactic category distinctions to distinctions of logical category, supplemented by lexical 'exception features' (e.g., verbs and adjectives would both belong to the category 'predicate,' usually confusingly called 'V' by GS-ists, with adjectives differing from verbs in bearing a feature licensing the application of a transformation that inserts a copula), while other generative grammarians took syntactic categories to have at most a tangential relation to semantic categories.
d. The linguistic level or levels relevant to the choice of the lexical material of a sentence. One who holds that there is no level of syntactic deep structure as distinct from semantic structure is forced to recognize syntactic structures whose ultimate units are semantic rather than morphological in nature, such as a syntactic structure [Brutus DO SOMETHING$_x$ (X CAUSE (BECOME (NOT (Caesar ALIVE))))] underlying *Brutus killed Caesar.* (Here and below, capitalization is used as an informal way of representing semantic units corresponding roughly to the words in question.) GS-ists accordingly proposed transformations that combined semantic units into complexes that could potentially underlie lexical items, e.g., 'predicate-raising' (proposed in McCawley, 1968) adjoined a predicate to the immediately superordinate predicate, thus allowing the derivation of such complexes as NOT-ALIVE, BECOME-NOT-ALIVE (= *die*), BECOME-NOT (= *cease*), and CAUSE-BECOME-NOT-ALIVE or CAUSE-*die* (= *kill*). Intermediate derivational stages involving both lexical and semantic units (such as CAUSE-*die*) needed to be recognized in order to account for, e.g., the parallelism between idiomatic combinations with *come* (*come about, around, to* . . .) and their counterparts with *bring*: as Binnick (1971) noted, *bring* corresponded not to CAUSE plus some determinate complex of semantic material but to CAUSE plus *come*, irrespective of whether *come* was used as an independent lexical unit or as part of such combinations as *come about*. Consequently, lexical insertion could not be restricted to a single linguistic level: applications of certain transformations had to be interspersed between lexical insertions. The combinations that could be derived through the application of predicate-raising and other 'prelexical' transformation were supposed to underlie 'possible lexical items.' Since there are infinitely many such combinations but only finitely many actual

lexical items in any given language, most correspond to no actual lexical item of the language and were supposed to reflect accidental gaps in the lexicon of the language.

Lexical decomposition analyses were criticized in such works as Fodor (1970), where it was argued that the simple and complex surface forms that supposedly corresponded to the same deep structure (e.g., *Brutus killed Caesar* and *Brutus caused Caesar to die*) did not in fact have the same meanings. It was noted subsequently (McCawley, 1978) that such discrepancies in interpretation can be explained by a version of Grice's (1967/1989) maxim of manner according to which a simple surface form is preferred to a more complex alternative except when the referent is a peripheral instance of the category defined by the given semantic structure, e.g., using indirect means to cause someone to die would be a peripheral instance of the category defined by 'cause to cease to be alive' and thus would not be in the part of that category where *kill* would preempt the use of *cause to die*. (Syntactic analyses involving lexical decomposition also figured prominently in Gruber, 1965, a work that early GS-ists found congenial despite some important differences between its framework and theirs.)

GS Policies on the Conduct of Research

Of equal importance to these points of theory in their influence on the directions that GS research took and the reception that GS work received were several policies about the conduct of linguistic research, of which the following deserve mention here:

a. A lack of concern about the compartmentalization of the parts of a linguistic analysis or of a linguistic theory, as contrasted with the concern among Chomskyan generative grammarians with the drawing of boundaries among, e.g., syntax, semantics, and pragmatics. One important facet of this lack of concern was an egalitarian position regarding the different kinds of data that had a bearing on a linguistic analysis: whereas most generative grammarians held that syntactic analyses needed to be supported by arguments in which only syntactic facts figured, GS-ists held that facts about truth conditions, possible denotations, etc., were as relevant as any other kind of facts to evaluating analyses that purported to specify how meanings corresponded to surface forms in the given language, and that supposed syntactic facts were usually at least partly semantic in nature, in that what a speaker of a language judges acceptable is not a sentence in itself but that sentence relative to an assumed understanding of it. Another facet of this policy was GS-ists' insistence that all parts of a linguistic analysis were subject to the same standards of explicitness, simplicity, and factual accuracy, irrespective of how one might wish to demarcate syntax and semantics; by contrast, interpretive semantics has come only gradually and often grudgingly to subject the semantic parts of analyses to the same standards of appraisal as the syntactic parts.
b. Rejection of the dogma of generative grammar that a fixed notational system is essential to a linguistic theory and that precision can be achieved only by formulating one's analyses in the privileged notational system.
c. Adoption of a 'static' conception of linguistic rules: rules were thought of not in terms of the popular metaphor of assembling linguistic structures and converting structures on one level into corresponding structures on another, but as 'derivational constraints,' that is, as specifications of what a structure may or may not contain and of how a structure on one level may not contain and of how a structure on one level may or must differ from the corresponding structure on another level. This difference in the conception of rules resulted in difference with regard to what theoretical notions posed 'conceptual problems' (Laudan, 1976) for each approach; thus GS-ists readily accepted rules that specified relations among nonadjacent levels of structure (what Lakoff, 1970b dubbed 'global rules'), a notion that was unproblematic from their conceptual vantage point but outlandish from the vantage point of the 'operation' metaphor for rules, while rejecting the idea of ordering among rules, a notion that was unproblematic for those who accepted the 'operation' metaphor but was difficult to make coherent with the GS conception of rules as derivational constraints.
d. Disdain for those concerns of Chomskyan generative grammarians that had little connection with linguistic facts or with detailed linguistic description, such as mathematical models and speculation about the extent to which linguistic structure is biologically determined. While GS-ists were receptive to the idea that linguistic structure is profoundly influenced by neuroanatomy, they demanded (e.g., Lakoff, 1974: 171) that claims to that effect be backed up with solid linguistic and solid biology rather than with what they dismissed as arguments from ignorance (i.e., hasty leaps from one's failure to see how some characteristic of languages could be learned to the conclusion that it must be innate).
e. Eagerness to put in practice in their professional lives many of the ideas of the 1960s counterculture,

such as policies of antiauthoritarianism, antielitism, and demystification of science and scholarship, and a belief that one's work should be pleasurable. One of many facets of the GS ethos that these policies helped to shape is what Newmeyer (1986: 133) has disparaged as 'data-fetishism': joy in the unearthing of novel and intriguing facts for which one is not yet in a position to provide a satisfactory analysis; GS-ists, by contrast, regarded Chomskyan generative grammarians as 'scientific Calvinists' (McCawley, 1980: 918).

Prominent and Influential Analyses Proposed within the GS Approach

Kuhn (1970) notes that one major component of the paradigm of a scientific community is a set of 'exemplars': prestigious solutions to problems, presented to neophytes in the field as paragons of good science, and serving as models for solutions to new problems. (For discussion of the history of generative grammarians' analyses of English auxiliary verbs in terms of Kuhnian notions such as 'paradigm' and 'exemplar,' see McCawley, 1985.) The exemplars for the GS community included a number of analyses that bore an intimate relation to central tenets of GS, for example, lexical decomposition analyses such as were discussed in, First section of this article, and analyses of quantified expressions as being external to their host sentences in deep structure (e.g., *John has read many books* = *many books* + *John has read x*) and as being moved into their surface positions by a transformation of Quantifier-Lowering (QL). (The term QL was in fact applied indiscriminately to a variety of transformations that differed according to the specific deep structure that was assumed; proposals differed with regard to whether just a quantifier or a whole quantified expression was external to the host S, what filled the deep structure position into which the quantified expression was to be moved, and where the quantifier or quantified expression was in relation to the host S.) The best-known arguments given for a QL analysis consisted in demonstrations that the many syntactic rules that were problematic when applied to structures that contained quantified elements became unproblematic if the deep structure position of a quantified expression was external to its host sentence and consequently (in virtue of the principle of the cycle) the rule had as its domain of application a structure that does not contain the quantified expression; for example, this view of the interaction between QL and the transformation of 'Reflexivization' explained why such pairs of sentences as *Every philosopher admires himself* and *Every philosopher admires every philosopher* differed in meaning in the way in which they did, and why reflexivization was applicable only in the derivation of the former. A thorough survey of arguments for a QL analysis is given in McCawley (1988: Ch. 18).

Several other GS exemplars were in fact as consistent with the substantive claims of interpretivist transformational grammar as with those of GS, but were embraced by GS-ists and rejected by interpretive semanticists as much because of policies on the conduct of research (see previous section) as because of any points of linguistic theory, or simply because of the historical quirk that a particular idea occurred to a member of the one camp before it occurred to any of his counterparts in the other camp. One such exemplar is the analysis of English auxiliary verbs as being verbs that take nonfinite sentential complements in the manner of such verbs as *seem* (Ross, 1969; McCawley, 1971), which Pullum and Wilson (1977) subsequently argued for from within an interpretive semantic framework. (A similar treatment of auxiliary verbs is found in Jespersen, 1937: 92). A second was the proposal (McCawley, 1970, subsequently disavowed by the author) that English had underlying verb–subject–object (SVO) word order, a hypothesis that is, if anything, harder to reconcile with the assumptions of GS than with those of interpretive semantics in view of the dubious nature of the assumption that the order of elements is significant in semantic structure; by contrast, there is no general policy in interpretive semantic versions of generative grammar against discrepancies between deep and surface constituent order, and indeed languages with surface VSO word order are commonly analyzed by interpretive semanticists as having deep VSO word order. Another such exemplar is the 'performative analysis' (Ross, 1970), in which sentences are assigned underlying structures in which a 'hypersentence' (Sadock, 1969, 1974) specifies the illocutionary force of the sentence, e.g., *Birds fly* would have an underlying structure of the form [*I tell you* [*birds fly*]].

The History of GS

The term 'generative semantics' first appears in Lakoff (1963/1976), a work that antedates the development of the Katz–Postal–*Aspects* approach to syntax and prefigures some of Lakoff's subsequent GS work. GS originated in attempts by Postal and Lakoff to exploit novel possibilities that were opened up by the revisions of the transformational syntactic framework proposed in Katz and Postal (1964) and Chomsky (1965) and to fill gaps in the evolving framework. For example, Lakoff's Ph.D. thesis (Lakoff, 1965/1970) originated as an attempt to develop a precise and coherent account of the way in

which a lexical item could affect the applicability of transformations to structures containing the given item, and thereby to put on a solider footing those analyses in Chomsky (1965) in which the choice of lexical items affected the possibilities for derivations. In the course of providing such a theory of 'rule model theory.) Coincidentally, the radical revisions that interpretive semanticists were making in their versions of generative syntactic theory included the adoption of the 'X-bar' conception of syntactic categories (see *X-Bar* Theory (*see* **X-Bar Theory**), which identified two of the factors that affect the syntactic behavior of a linguistic unit, namely, the difference between a word unit and a phrasal unit, and the part of speech of the unit or of its head. Once a descriptive framework was available that allowed linguistic generalizations to be stated in terms of those factors, considerable progress was made in the analysis of the many syntactic phenomena in which those factors play a role.

No important tenets of GS rule out the adoption of a conception of syntactic categories as defined by these factors *in addition to* logical categories, and indeed a conception of syntactic categories as reducible to those and other factors (with logical category being merely one of several factors that influence a unit's syntactic behavior) is adopted in McCawley, 1977/1982 and subsequent works. However, in the 1960s and early 1970s, an assumption shared by GS-ists and interpretive semanticists impeded GS-ists from adopting such a conception of categories, namely the assumption that syntactic categories must remain constant throughout derivations: a word (with a determinate part of speech) that replaced a complex of semantic material (thus, a unit not having a part of speech) could not differ in category from the replaced unit and thus parts of speech could not be part of the category system. (The widespread misconception that GS analyses allowed linguistic units to change category in the course of derivations in their analysis of, for example, nominalizations overlooks the fact that, according to GS-ists' assumptions, verbs and their nominalizations belonged to the same category. Anyway, analyses of any kind in which the verb *invent* is a constituent of the noun *invention* are not committed to any assumption that the former changes its category in the derivation of the latter: it is whatever it is, regardless of what it is contained in.) Since interpretive semanticists did not require that deep structures match semantic structures (and indeed took delight in arguing that they did not match), there was no obstacle to their having the same categories in deep as in surface structures while drawing the full range of category distinctions provided for by X-bar syntax. The interpretive semantic research program was thus able to become 'progressive' in the sense of Lakatos (1978) because of something extraneous to the issues that were the loci of the substantive disputes between GS and interpretive semantics.

Forms of Generic Reference

Generic reference is the term commonly used to describe noun-phrase reference in sentences that express generalizations (*see* **Generics, Habituals and Iteratives**). Some common examples are found in (1)–(3):

(1) *Potatoes* are native to South America.

(2) *The lion* is a fearsome beast.

(3) *A pencil* is used for writing.

Generic reference is usually understood as making reference to kinds of things (*see also* **Natural Kind Terms**). When we speak of 'kinds,' we intend a classification system that is based on the denotations of nominal expressions, or sortals, of the language (for one view, see Gupta, 1980).

It is now commonly accepted that reference is not only limited to individuals or pluralities of individuals, but also to kinds or types of things as well. This is most evident in noun phrases of the type "this kind of animal," which evidences an overt postdeterminer of the class of 'kind,' 'type,' 'sort,' 'species,' and so on.

(4) *This kind of animal* hibernates in the winter.

These kind-referring phrases can appear in quantified contexts as well. The analysis then is that the quantifier ranges over kinds of things, just as it ranges over individuals in the more usual instances.

(5) *Three kinds of swallows* are found in the northeastern United States.

(6) *Every type of tree* exchanges carbon dioxide for oxygen.

When the postdeterminer element is removed, there remains the possibility of interpreting the noun phrase as referring to or quantifying over kinds. This normally results in a type/token ambiguity. For instance, in (7) one could be talking about individual flowers in a given context or kinds of flowers; similarly for (8). This reading is called a *taxonomic reading* in Krifka *et al.* (1995).

(7) Sharon photographed *every flower.*

(8) *Several penguins* inhabit this frozen wilderness.

Examples such as (7) and (8) are ambiguous between a 'kind' reading and the more common individual reading. On the taxonomic reading, the denotation of the head noun is partitioned into subkinds, though this is done contextually since there are multiple ways to naturally partition any domain. For instance, automobiles can be partitioned according to body style (sedan, sports car, station wagon, etc.) or by manufacturer (BMW, Mazda, Volvo, etc.), among other ways. It is commonly noted that if one takes a mass term and syntactically treats it as a count term, by pluralizing it or pairing it with a determiner that selects for singular count nouns only, a taxonomic reading may emerge. Thus, in (9) we are speaking of kinds of wine, and in (10) of kinds of metal:

(9) *Three wines* are stored in the cellar.

(10) *Every metal* conducts electricity to some degree.

Another means by which kinds are referred to in natural language is by definite singular noun phrases. In English, this has a stylistically technical tone, but this is not a general feature of other languages. Three possible examples are:

(11) *The computer* has changed society in many ways.

(12) Scientists have now documented the entire life cycle of *the three-toed sloth*.

(13) *The self-cleaning plow* was invented by John Deere.

These exemplify the definite generic on the most natural readings of the noun phrases in these examples. This reading appears in addition to the much more frequent individual-denoting use of the definite article, and often results in ambiguity. Generally unambiguous is the use of the definite article with only an adjective (e.g., "*The rich* are often oppressors of *the poor*"). Other types of definite kind reference include uses of the proximal and distal demonstratives (*this, that*) in the plural. The demonstrative is not, on one interpretation, an actual indexical; instead, it colloquially conveys an emotional attitude toward the kind (Bowdle and Ward, 1995). It appears to be the same use of the demonstrative as when it accompanies a proper name (e.g., "*That Roberto* has done it again").

(14) *Those spotted owls* (i.e., the kind spotted owl) are constantly being talked about by environmentalists.

(15) Who invented *these computers*, anyway?

In addition, there are noun phrases that employ adjectives like 'typical,' 'average,' or 'normal,' which have a kind-reference reading, as in "*Your typical businessperson* takes eight plane trips per year." Supplementing definite generics are the consciously introduced Latinate natural kind names, lacking a definite article, which always have an elevated scientific tone no matter the language. This includes examples like *'felis domesticus'* (cat) or *'acer saccharum'* (sugar maple tree). These are unambiguous and always denote kinds. Though not of consciously Latinate origin, the use of 'man' in English as a generic functions in much the same way.

Beyond these are additional means of kind reference in natural language. Bare plurals – that is, plural noun phrases lacking a determiner or quantifier element, at least on one reading – may refer to kinds. The following are three examples:

(16) *Airplanes* have made intercontinental travel a common event.

(17) *Lions* once ranged from the tip of Africa to eastern Siberia.

(18) *Hunting dogs* are most closely related to *wolves*.

Functioning much the same as bare plurals are undetermined mass expressions (in French, the definite article must be employed), which allow for generic reference to unindivuated domains.

(19) *Water* is a liquid. (cf. Fr. "*L'eau est un liquide.*")

(20) *Hydrogen* is the most common element in the universe.

Finally, the singular indefinite article allows for a generic usage, as in the following:

(21) *A triangle* has three sides.

(22) *A potato* contains vitamin C.

The bare plural and the indefinite singular are commonly distinguished from the definite singular in English in that the former two usually allow for additional descriptive material in the form of modification, whereas the noun phrases in the definite generic instance are much more limited.

(23) *A cake without baking powder/Cakes without baking powder/??The cake without baking powder* fails to rise properly in the oven.

Unlike the bare plurals or indefinite singulars, the definite singular is basically limited to expression of well-established kinds, those taken to be already familiar from one's background knowledge. Furthermore, as Vendler (1971) notes, it does not appear they can be 'too general.' Thus, alongside 'the parabola' and 'the circle,' one does not find generic reference to 'the curve.' Currently, a full account of these facts is lacking.

Cross-linguistically, generic reference is carried out by noun phrases with definite and indefinite articles and with determinerless expressions quite generally. In languages without articles, the determinerless form typically has a generic interpretation in at least some sentence positions. While in English the plural form of the definite has generic reference only marginally at best, in German, which is closely related to English, the plural definite may take generic reference quite easily (Delfitto, 1998). If there are languages with articles or other determiners specific to generic reference, they have yet to be brought to general attention, or they may not exist at all.

It is important to distinguish generic reference from the type of sentence in which the expression appears. While generic reference takes place most commonly within the context of a generic or habitual sentence, not all generic or habitual sentences have a noun phrase with generic reference, and generic reference may take place within sentences that are episodic or that make reference to specific events. The clearest examples of this are sentences with the definite singular generic exhibiting the *avant-garde* reading (Krifka *et al.*, 1995). Consider the following example:

(24) *The horse* arrived in the New World around 1500.

This means that some horses were introduced about that time, but implies that the event was the first time any modern horses had been in that area. To observe a shipment of horses arriving in the western hemisphere in 1980 and use (24) modified by "in 1980" to describe that event would be inappropriate. Other instances where there is kind-reference in episodic sentences, on at least one reading, include the following three examples:

(25) Today, Professor James lectured to us on the history of *dinosaurs*.

(26) Marconi invented *the radio*.

(27) *Monkeys* evolved from *lemurs*.

Theory of Generic Reference

While most semanticists agree that at least certain noun phrases refer to (or quantify over) kinds of things, there is a tradition in which apparent kind reference is treated in terms of quantification over individuals. Stebbings (1930), for instance, suggests that the sentence "The whale is a mammal" expresses a universal proposition (similar to "All whales are mammals"), as does "Frenchmen are Europeans." Russell comments that the sentence "Trespassers will be prosecuted" "means merely that, if one trespasses, he will be prosecuted" (1959: 102), which reduces the analysis of the apparent kind reference (*trespassers*) to an indefinite in a conditional. However, Moore (1944), in response to Russell's theory of descriptions, cites examples like "The triangle is a figure to which Euclid devoted a great deal of attention" and "The lion is the king of beasts," both of which convincingly resist implicit quantificational or conditional analyses.

The most convincing evidence for kind reference in the semantics stems from predicate positions that select for something other than individuals and pluralities of individuals and that readily accept the types of noun phrases reviewed earlier. These are called kind-level predicates. Examples (26) and (27) contain kind-level predicates. While an individual might invent something, the direct object must express a kind of thing and not a particular individual or set of individuals. The verb 'evolve' relates species and other levels of biological classes to other such classes,

but not individuals to individuals. The following are other examples of kind-level predicates:

(28) Dogs are *common/widespread/rare*.

(29) Insects are *numerous*.

(30) The elm is *a type/kind of tree*.

(31) The gorilla is *indigenous to* Africa.

(32) The Chevrolet Impala *comes in* 19 different colors.

Kind-level predicates are relatively infrequent in any language. Most predicates fall into the classes of either individual level or stage level. Roughly speaking, stage-level predicates speak of highly temporary events and states, such as running across a lawn, eating a sandwich, or being asleep. Individual-level predicates, on the other hand, speak of more permanent states of affairs, such as knowing French, liking the opera, or being intelligent. Typically, the predicates of a habitual or generic sentence ("x cooks wonderfully") are individual level. These are discussed in more detail in Carlson (1980), Kratzer (1995), Fernald (2000), and by others. Both stage-level and individual-level predicates select for noun phrases that denote individuals and pluralities of individuals. However, kind-denoting expressions appear with these predicates naturally as well. With both stage-level and individual-level predicates, a quantificational analysis of kind-denoting phrases (quantifying over individuals of that kind) becomes easily possible.

The kind-level predicates do not typically allow for the use of the indefinite singular. An example like (33) is generally deemed not very acceptable:

(33) ?*A lion* is a species of animal. (cf. *the lion, lions*)

A continuing controversy centers on the analysis of the English bare plural construction, which has an unlimited distribution in comparison to bare plurals in other languages with articles, such as Spanish or Italian (e.g., Laca, 1990). English bare plurals appear to have different interpretations in different contexts. With individual-level predicates, they have a general interpretation, one that is quantificationally similar to 'all' or 'most.'

(34) Cats (roughly, all or most cats) sleep a lot.

(35) Hammers (roughly, all or most hammers) are used for driving nails.

On the other hand, bare plurals also have an existential interpretation in other contexts that is similar to "some" in force.

(36) *Priceless works of art* (i.e., some works) were delivered to the museum yesterday.

(37) The rioters threw *stones* through *shop windows*, shattering them.

The primary question is whether in these instances, as well, the bare plural construction is kind-denoting, as most believe it is with kind-level predicates. Carlson (1980) and Chierchia (1998) argue that such a unified analysis is not only possible but also desirable, and both present analyses showing how it can be accomplished. However, others argue that more adequate insight can be gained through an analysis that differentiates true instances of kind reference from those instances where bare plurals appear with individual-level and stage-level predicates and that a quantification over individuals approach is better taken (see Wilkinson, 1991; Diesing, 1992; Krifka *et al.*, 1995).

Generics, Habituals and Iteratives

G Carlson, University of Rochester, Rochester, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Sentences may express information about particular events, such as:

(1) Mary ate oatmeal for breakfast this morning

But sentences can also express regularities about the world that constitute generalizations over events and activities:

(2) Mary eats oatmeal for breakfast

Unlike (1), the truth of (2) does not depend on Mary eating oatmeal for breakfast at any particular time and place, but instead it is the regularity of occurrence that is asserted, and the truth conditions of the sentence are tied to that regularity.

Sentences of the sort exemplified in (1) are sometimes called 'episodic' sentences. The class of episodic sentences also includes examples where a plurality of individuals or events occurs. The examples (3–5) exemplify sentences that are episodic but whose truth values depend on multiple occurrences of particular events:

(3) Mary and George ate oatmeal for breakfast
(4) Each student in the class handed in a completed assignment
(5) Every day last week, Mary ate lunch at a restaurant

Such examples are episodic. In contrast, examples such as (1) are often called 'habitual' or 'generic' sentences. In some instances, habituals are termed 'iteratives,' but insofar as the terminology indicates that iteratives and habituals are the same thing, it can be misleading (see Comrie (1976: 27) for extended comments on the use of the term in Slavonic linguistics). Iteratives are a subclass of aspectual operators and do not produce generic or habitual sentences but rather are episodic in nature. Payne describes iteratives in the following way: "Iterative aspect is when a punctual event takes place several times in succession" (1997: 39). That is, what is produced is a series of events of the same type, which occur in a sequence (i.e., not simultaneously) and are intuitively connected with one another in time (i.e., not spaced 'too far' apart). Such iterative interpretations are especially common for semelfactive verbs such as *cough* or *flap* (*a wing*). In English, *John coughed* can be understood as saying that he coughed once, or in a series, repetitively. In some languages, iteratives are marked morphologically, typically by an inflectional affix on the verb though commonly in other ways such as by reduplication, as in Quileute (Greenberg *et al.*, 1978). Iteratives, when specifically marked, also lend themselves to additional implications, especially those of intensity and/or prolongation. In English, *John coughed and coughed* is iterative in interpretation, like one understanding of the simple *John coughed*, but in addition implies that he coughed each time with intensity and/or that he coughed for a prolonged period. Often there are implications that the intensity or prolongation is inappropriate or a sign that something is wrong. These implications, however, are not a part of iterativity *per se*, but an additional, associated meaning above and beyond.

Generics, Habituals and Iteratives

G Carlson, University of Rochester, Rochester, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Sentences may express information about particular events, such as:

(1) Mary ate oatmeal for breakfast this morning

But sentences can also express regularities about the world that constitute generalizations over events and activities:

(2) Mary eats oatmeal for breakfast

Unlike (1), the truth of (2) does not depend on Mary eating oatmeal for breakfast at any particular time and place, but instead it is the regularity of occurrence that is asserted, and the truth conditions of the sentence are tied to that regularity.

Sentences of the sort exemplified in (1) are sometimes called 'episodic' sentences. The class of episodic sentences also includes examples where a plurality of individuals or events occurs. The examples (3–5) exemplify sentences that are episodic but whose truth values depend on multiple occurrences of particular events:

(3) Mary and George ate oatmeal for breakfast
(4) Each student in the class handed in a completed assignment
(5) Every day last week, Mary ate lunch at a restaurant

Such examples are episodic. In contrast, examples such as (1) are often called 'habitual' or 'generic' sentences. In some instances, habituals are termed 'iteratives,' but insofar as the terminology indicates that iteratives and habituals are the same thing, it can be misleading (see Comrie (1976: 27) for extended comments on the use of the term in Slavonic linguistics). Iteratives are a subclass of aspectual operators and do not produce generic or habitual sentences but rather are episodic in nature. Payne describes iteratives in the following way: "Iterative aspect is when a punctual event takes place several times in succession" (1997: 39). That is, what is produced is a series of events of the same type, which occur in a sequence (i.e., not simultaneously) and are intuitively connected with one another in time (i.e., not spaced 'too far' apart). Such iterative interpretations are especially common for semelfactive verbs such as *cough* or *flap* (*a wing*). In English, *John coughed* can be understood as saying that he coughed once, or in a series, repetitively. In some languages, iteratives are marked morphologically, typically by an inflectional affix on the verb though commonly in other ways such as by reduplication, as in Quileute (Greenberg *et al.*, 1978). Iteratives, when specifically marked, also lend themselves to additional implications, especially those of intensity and/or prolongation. In English, *John coughed and coughed* is iterative in interpretation, like one understanding of the simple *John coughed*, but in addition implies that he coughed each time with intensity and/or that he coughed for a prolonged period. Often there are implications that the intensity or prolongation is inappropriate or a sign that something is wrong. These implications, however, are not a part of iterativity *per se*, but an additional, associated meaning above and beyond.

It is also commonly noted that progressive or continuous aspectual constructions often imply iteration. In *The bird is flapping its wings* the most natural interpretation is that there is a series of wing flappings (though an extended single flap might also be described in this way). But again iteratives are not the same as progressive and continuous constructions, having different and distinguishable semantic contents.

Unlike iteratives, habituals and generics do not denote a connected series of events, even though there is the root intuition that repetitiveness is involved. Terminology is not entirely standardized; one also finds the terms 'customary,' 'usitative,' 'gnomic,' and 'frequentative' applied to generics and habituals, though occasionally with more specialized meanings. The term generic predominates in the formal semantics literature and habitual appears most dominant in the more descriptive literature. Some reserve the term generic for habitual sentences with subject noun phrases that have generic rather than specific reference (*see* **Generic Reference**), though this is not standard practice. The term habitual itself is potentially misleading. Lyons notes that, "The term 'habitual' is hallowed by usage; but it is something of a misnomer in that much of what linguists bring within its scope would not generally be thought of as being a matter of habit" (1977: 716). The following examples would also qualify as habituals according to the general pattern of usage:

(6) Glass breaks easily (a disposition)
(7) Bishops move diagonally (a rule of a game)
(8) Robert works for the government (an occupation)
(9) Soap is used to remove dirt (a function)
(10) A wise man listens more than he speaks (a moral injunction)

Like iteratives, generics and habituals may be morphologically marked, normally by an inflectional affix or a free form in the verb's 'auxiliary' complex, though also through a wide variety of other formal means. Habitual markers are typically classified as a member of the aspectual system, though this morphological marking is in addition to the variety of means lexically available (e.g., 'tends to,' 'has a habit of') and is a component of meaning of most frequency adverbs such as *usually*, *often*, or *always*. Payne (1997) cites the example of Ewe:

(11) É-du-a mɔli
3sg-eat.HAB rice
'S/he eats rice'

Dahl (1985) in a cross-linguistic survey notes similar marking in Guarani (Paraguayan Guaraní), Georgian, Kammu (Khmu), Czech, Akan, Wolof, and other languages. Similar markers can be found in a wide variety of other languages, noted in specific studies (e.g., Swahili, Guyanese English, Tamazight, Awa, Zapotec (Istmo Zapateco), Navajo). These co-occur with predicates classified as events and processes, but not, in general, with stative predicates. Most commonly, though, in languages that have specific morphological expression of habituality, one can also express habituality via a regular (usually tensed) form, often in the imperfective if the language makes an imperfective/perfective distinction, though also very commonly in the maximally unmarked tensed forms of the language (Dahl, 1995). Semantic differences are occasionally noted in languages that have a marked and an unmarked expression of habituality, but little research has been conducted on this question. One particular form appears with considerable regularity. This is a specialized remote past tense form, functioning like English *used to*. Further, formal distinctions not associated with the auxiliary and inflectional system of the verb also may be reflective of a habitual/episodic distinction, as in the *wa/ga* distinction in Japanese, the *når/da* 'when' distinction in Norwegian, or the *ser/estar* distinction in Spanish. Though on occasion iterative forms and habitual forms are identical, this is not indicative of any special semantic connection as more commonly languages use syncretic future forms, progressives, and imperfectives to express habituality, among a wide variety of other possibilities.

Whereas generics and habituals appear to make reference to a multiplicity of events, reminiscent of the episodic examples in (3–6) or iteratives, generics and habituals are quite different in character. For one, the resultant sentence is aspectually stative (though derived from a nonstative) or at least shares major properties with other statives. For instance, in a narrative discourse a generic sentence does not 'move' the time forward, as do events and processes, but rather, like other instances of statives, appears to provide background or setting information. Like statives, generics and habituals also observe the subinterval property (Dowty, 1979). That is, if a habitual is true for a period of time, it is also true for any smaller interval within that same period of time, no matter how short.

Generics and habituals also have, as pointed out by Dahl (1975), an intensional component of meaning lacking in episodics. This intensionality may be observed, in part, in the 'nonaccidental' understanding of generics and habituals. This is the notion that the varying events generalized over are a part of a larger generalization, and not some happenstance (Schubert and Pelletier, 1987). For example, imagine you

encounter some very, very small town in which all residents, entirely unbeknownst to one another, chew (only) sugarless gum. It could be sheer happenstance, but if one accepts the following as true:

(12) Residents of this town chew sugarless gum

one commits to the notion that this is not sheer happenstance, but that there is some underlying cause or causes of this particular behavior (e.g., the town dentist instructs people to avoid sugared gum; it is the only brand the local store carries). The particular cause or causes need not be specifically identified, but it does give rise to the counterfactual implication that if a person were to become a town resident, he or she too would likely chew sugarless gum, as a result of becoming a town resident, even if they had not done so before.

Being generalizations, generics and habituals also have the property of tolerating exceptions. The initial instinct is to treat generics and habituals as universally quantified sentences. However, if you learn that Elena eats oatmeal for breakfast, she need not eat oatmeal at every breakfast. Or, the commonly found example *Birds fly* is tolerant of exceptional penguins, ostriches, and other flightless birds. The limits of this exceptionality has proven extremely difficult to quantify—how long must Elena go without eating oatmeal for breakfast before the generalization no longer holds? How many flightless birds need there be in order for *Birds fly* no longer to be thought true? While some quantitative understanding of exceptionality plays a role, most researchers agree that generics and habituals require an additional component of meaning, or a different arrangement of meaning altogether, to give an account of exceptionality.

The most commonly assumed semantic analysis of habituals and generics is outlined in Krifka *et al.* (1995). This is a fundamentally quantificational analysis of habitual sentences. It posits an operator, which is often implicit in the linguistic form, which is a dyadic relation between the interpretations of two constituents partitioned from the sentence it is operating on, a 'restrictor' and a 'matrix' or 'nuclear scope,' in keeping with the most commonly accepted semantic analysis of quantification. As this dyadic operator is focus-sensitive, generic sentences can be ambiguous, according to which constituent meaning is assigned to the restrictor and matrix. For example, Milsark (1974) notes the ambiguity of the sentence *Typhoons arise in this part of the Pacific*. As discussed in Carlson (1989), if the subject noun phrase *typhoons* is understood as the restrictor, and the predicate of the sentence is understood as the matrix, then the interpretation assigned is akin to asserting that generally speaking, if something is a typhoon, it then arises in this part of the Pacific ocean (and not elsewhere). If, on the other hand, *in this part of the Pacific* is assigned to the restrictor, then the resulting interpretation is that, in this part of the Pacific, there arise typhoons (from time to time), and perhaps elsewhere as well. Word order in English and other languages can affect how the sentence is partitioned by this and other focus-sensitive operators (Diesing (1992) discusses German (Standard German) at some length). For instance, the English sentence *In this part of the Pacific arise typhoons* has only the latter of the two readings.

Krifka *et al.* (1995) describe the generic operator as a "default quantifier" in order to account for exceptionality and intensionality. Other researchers take a different approach, such as modifying possible worlds to enrich the interpretive structure with a notion of 'normality' or 'prototypicality' (e.g., Eckhardt, 2000; Heyer, 1987). The basic idea here is that one can reduce the generic operator to a universal statement relativized only to the most typical or normal individuals of the domain, or to "normal worlds." Cohen (1999) suggests that the generic operator is a quantificational operator similar in contents to 'most,' though relativized to a partition of individuals and situations that is pragmatically driven, and not determined by the focus structure of the sentence. For instance, in asserting that mammals bear live young, one is partitioning the set of mammals by gender and age, as only mature (fertile) females have such capability. Meanings of habituals and generics are often expressed in Artificial Intelligence and Computer Science by way of default reasoning systems and non-monotonic logics. Such systems are designed to draw logical conclusions in the face of absence of information. According to this understanding then, a generic or habitual is information assumed to hold for any given relevant instance, unless specific information is given otherwise.

The Genetic Underpinnings of Language

Many modern linguistic theories assume that at least some aspects of our linguistic behavior are genetically determined: Chomsky's early arguments from the poverty of the stimulus (for example, Chomsky 1988) set out the position that children could not learn any language as quickly and completely as they do, with so many shared intuitions, and on the basis of such relatively partial and degenerate data, in the absence of some innate, prespecified assistance. The precise configuration of this innate component, which is often called Universal Grammar or the language faculty, has been much debated; for a recent, much-discussed contribution to this literature, see Hauser, Chomsky, and Fitch (2003).

However, the advent of molecular genetic technology and the human genome project have made it possible to ask a more direct question: what exactly are the genes that underlie language and make humans linguistic animals? As often in the history of science, the main attempts to address this question have involved studying systems where things have gone wrong.

It is well known that certain individuals have significant difficulties in acquiring and using language. Such difficulties may or may not be correlated with other developmental disorders: in Williams Syndrome, for example, there are other nonlinguistic deficits, while in so-called SLI, Specific Language Impairment, nonlinguistic aspects of development are frequently within the normal range. This feature makes SLI a good candidate for identification of a gene or genes associated with language development as opposed to general cognitive capacities, if and only if SLI or similar conditions can also be shown to be inherited and therefore likely to be at least partially genetically determined.

The key to the story of one particular candidate gene is the so-called KE family, whose case is discussed in Fisher *et al.* (1998) and elsewhere. About half the members of this family, over three generations, have suffered from a range of speech and language problems, including severe difficulties with articulation, and with the use of affixes to signal grammatical information including tense and agreement (Gopnik, 1999). Because this syndrome of deficits, referred to as developmental verbal dyspraxia, is inherited in a dominant fashion (meaning that each affected individual has one affected parent), it was relatively straightforward to identify the gene involved. The first step was to track this gene to

The Genetic Underpinnings of Language

Many modern linguistic theories assume that at least some aspects of our linguistic behavior are genetically determined: Chomsky's early arguments from the poverty of the stimulus (for example, Chomsky 1988) set out the position that children could not learn any language as quickly and completely as they do, with so many shared intuitions, and on the basis of such relatively partial and degenerate data, in the absence of some innate, prespecified assistance. The precise configuration of this innate component, which is often called Universal Grammar or the language faculty, has been much debated; for a recent, much-discussed contribution to this literature, see Hauser, Chomsky, and Fitch (2003).

However, the advent of molecular genetic technology and the human genome project have made it possible to ask a more direct question: what exactly are the genes that underlie language and make humans linguistic animals? As often in the history of science, the main attempts to address this question have involved studying systems where things have gone wrong.

It is well known that certain individuals have significant difficulties in acquiring and using language. Such difficulties may or may not be correlated with other developmental disorders: in Williams Syndrome, for example, there are other nonlinguistic deficits, while in so-called SLI, Specific Language Impairment, nonlinguistic aspects of development are frequently within the normal range. This feature makes SLI a good candidate for identification of a gene or genes associated with language development as opposed to general cognitive capacities, if and only if SLI or similar conditions can also be shown to be inherited and therefore likely to be at least partially genetically determined.

The key to the story of one particular candidate gene is the so-called KE family, whose case is discussed in Fisher *et al.* (1998) and elsewhere. About half the members of this family, over three generations, have suffered from a range of speech and language problems, including severe difficulties with articulation, and with the use of affixes to signal grammatical information including tense and agreement (Gopnik, 1999). Because this syndrome of deficits, referred to as developmental verbal dyspraxia, is inherited in a dominant fashion (meaning that each affected individual has one affected parent), it was relatively straightforward to identify the gene involved. The first step was to track this gene to

a small region on the long arm of chromosome 7 (Fisher *et al.,* 1998); mutations in this region were identified in affected family members in a gene now named FOXP2, and details were published in Lai *et al.* (2001). FOXP2 appears more generally to be involved in the development of the brain, and has been shown, as is the case with many important genes, to be highly conserved in evolutionary terms. Enard *et al.* (2002) have established that FOXP2 is almost identical between mice and primates, with only one amino acid substitution; but there are two more changes between humans on the one hand, and other primates on the other. This difference means that mice and primates are separated by at least 130 million years and one genetic change, while humans and chimps, separated by just 5 million years, have two further changes (Chen and Li, 2001). It has therefore been argued that FOXP2 is highly likely to be implicated in the development of some system that differs substantially between humans and other primates; clearly, language is one such system.

This theory is a wonderful piece of scientific detective work, but there have been, as is often the case, overenthusiastic interpretations of the results, especially in the media, to the effect that **the** gene for speech and language has now been discovered. There are both specific and general objections to this line of argument. First, there are complex possibilities of cause and effect (Bishop, 2002). Might the apparent grammatical difficulties of members of the KE family be a consequence of their speech impairment? Are cognitive abilities in affected individuals really normal, or are they typically lowered, meaning that the supposedly isolated speech and language deficits might not be so isolated after all? The same complexities apply when we turn to the evolutionary relevance of FOXP2: is the gene implicated in the origins of language, or in the improvement of vocal communication for an elementary system that had already developed? Even if we accept that FOXP2 is the only gene involved in this deficit for this family, there are certainly individuals with SLI who do not show any defect in FOXP2, though some other possible candidate regions on chromosomes 16 and 19 are emerging (SLI Consortium, 2002).

More generally, it is highly unlikely that any complex system like language will involve only a single gene; many systems, both physical and neurological, are implicated in our linguistic abilities and behavior, and each may be controlled by the interaction of many genes. At least 20 genes are involved in the formation of blood clots, a relatively straightforward physical process: leaving aside the additional genes responsible for regulating the expression levels of these core 20, we should anticipate greater complexity in a complex, multisystem trait like language. Further implicated genes will certainly be found as more families are studied, and these will contribute to fuller understanding of the genetic underpinnings of the physical and neurological aspects of language; but the story will not be simple, and it is going to take a great deal of piecing together.

One thing linguists must remember, however, is that if we implicate genes and identify or theorize about some genetically specified language faculty, we are necessarily making evolutionary assumptions. Anything in our genes must have got there somehow in evolutionary time, either as a new structure, or more likely, as a development of an existing, older structure that may have had a tangentially related or altogether different function. The advent of genetic linguistics in this sense should make linguists consider carefully whether they wish to use terms like 'innate'; we should do so only if we are content for the gene hunters to look for the genetic structures behind them, and if we are confident that a truly universal, evolutionary explanation is plausible and necessary.

Genes and Languages in Populations

Modern genetics is divided into molecular and population subdisciplines. The former focuses on analysis of individual genomes, though the conclusions may be extrapolated to the species level; and the linguistic relevance of molecular studies was dealt with in the last section. At the population level, geneticists are not so much concerned with localizing and tracking individual mutations, but with the distribution of resulting variants within and between human (or other) groups. There will rarely if ever be a single mutation that uniquely characterizes all, or even most members of a population, since 84% of human genetic variations are found in all human groups (Barbujani, 1997); but by considering a whole range of genetic variants and calculating their frequencies, it is possible to produce a profile for each population and to work out how close this group is to others. Using the more quickly mutating mitochondrial or Y-chromosome DNA can also allow individual mutations to be tracked back to common ancestors, allowing the histories of populations and their interrelationships to be established.

For historical linguists, the important point is that the distribution of genes and languages may correlate across populations. This point straightforwardly reflects the fact that humans both carry genes and speak languages, and will therefore take both with them when they migrate, and potentially contribute elements of both when they interbreed with members of other populations. Because human histories are

complex and involve decisions about allegiance and group membership rather than simply stochastic processes, genetic and linguistic signals will not always match: in some situations, genetic signals may indicate earlier mixing of two populations, but the language of one original group may have been lost entirely, for instance. As contact between populations becomes more common over longer distances, the correlations between genes and languages are also likely to break down progressively, as indeed are boundaries between traditional groups in many parts of the world. However, it has been demonstrated that correlations between genetic and linguistic characteristics of populations can be found and explored (Poloni *et al.,* 1997; Gray and Jordan, 2000; Rosser *et al.,* 2000; McMahon, 2004; McMahon and McMahon, forthcoming). As one might expect, these hold best for populations separated by considerable distances or natural geographical barriers, and are more elusive for adjacent populations with a history of contact. Even here, however, comparisons of genetic and linguistic characteristics can be used productively as part of the 'new synthesis' (Sims-Williams, 1998; Renfrew, 1999; Cavalli-Sforza, 2000), for instance, in seeking to explain discrepancies by invoking particular patterns of contact or influence.

Work of this kind is interesting, not only or even principally because of the establishment of correlations, but because our insights into early history and prehistory from any individual discipline can be limited and hazy. If related historical disciplines, like population genetics, archaeology, and comparative linguistics, can cooperate and share results and interpretations, we are likely to achieve greater understanding of population histories. This research is aided by the recent and ongoing development of quantitative historical linguistics (Embleton, 1986; Ringe *et al.,* 2002; Gray and Atkinson, 2003; McMahon and McMahon, 2003, forthcoming), where computer simulations, and tree-drawing and simulation programs often developed initially in biology are applied to linguistic data to form, test, and validate hypotheses about relatedness and contact between languages. The development of programs that generate either trees or more complex networks depending on the signal pattern at issue (Bandelt *et al.,* 1999; Bryant and Moulton, 2004; Bryant *et al.*, forthcoming), and which therefore do not force a tree on nontreelike data, are particularly valuable and promising in allowing borrowing and common ancestry to be explored and represented as equally likely and important.

Geneva School of Linguistics after Saussure

L de Saussure, University of Geneva, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

After Saussure's death, the approach he founded developed into several competing versions of structuralism. The Geneva School of linguistics (a term first used during a gathering in 1908), being the depositary of the original Saussurean documents, and having edited and published the *Cours de linguistique générale*, focused on two main directions of research. First, scholars were concerned with interpreting and reconstructing Saussure's original thought, which remained unclear on several important points. Second, they launched and developed new research projects in areas that Saussure envisaged but did not pursue, such as linguistics of *parole* (related to pragmatics) as opposed to *langue* (related to the linguistic system).

The major figure within this trend is Charles Bally (1865–1947, co-editor of the periodical *Cours* with Albert Sechehaye), one of Saussure's disciples. Although he was deeply attached to the idea of a *langue* that needed to be studied from a static point of view, his research was pragmatic before its time. He was soon concerned with problems of *parole* (language-in-use), in particular in everyday spontaneous speech, a project he presented in his 1913 inaugural lecture. In Bally's three main publications, *Traité de stylistique française* (1909), *Le langage et la vie* (1913b), and *Linguistique générale et linguistique française* (1932), he focused on nonpropositional issues such as affective aspects of communication. In particular, he differentiates between the dictum (the content) and the modus (how this content is presented). Differences in the modus are differences about the attitude the speaker adopts toward the proposition conveyed, an idea which is to be related to his technical notion of *style*.

Bally's concept of style is understood as the mark of a subjectivity expressed through the packaging of the informational content. His idea was that content can be conveyed according to various *modalities*. Well before Bakhtin's work became popular in pragmatics, Bally posited not only that an utterance bears the trace of viewpoints, but also that, generally speaking, utterances are echoing other utterances and mixing viewpoints from several real or imaginary speaking instances. This idea converged with notions further developed in pragmatics and discourse analysis such as polyphony and heterogeneity of discourse. His theoretical work goes hand-in-hand with a reflection on Saussurean notions such as *value* and *signification*, about which he developed original thoughts (in particular, he suggests a dichotomy between *actual* concept in *parole* and *virtual* concept in *langue* in a 1940 paper). Charles Bally was also concerned with the didactics of first language, and gave a series of lectures at the University of Geneva on that topic in 1930, where he adopts, as a follower of Saussure, a moderate anti-normative position and pleads for a more synchronic point of view (reprint Bally, 2004).

Albert Sechehaye's (1870–1946) main theoretical work, illustrated with French data, was to suggest a renewal of the theory of grammar by means of a constructive method, considering that complex syntactic forms can be reduced to basic syntactic forms (Sechehaye, 1926).

The other scholars of the Geneva School are Robert Godel, who focused on the edition of Saussurean archives and discussed, in light of them, key Saussurean concepts; Serge Karcevski, who exported the ideas of the Geneva School to the Moscow School; Henri Frei, who worked on Asian languages and on a theory of mistakes in communication (Frei, 1929); Luis Prieto, who, following a first move toward social psychology, understood semiology in relation with social practices (Prieto, 1975); André Burger, who studied romance languages; and René Amacker, who established close links with the Italian school of linguistics

Differences in the modus are differences about the attitude the speaker adopts toward the proposition conveyed, an idea which is to be related to his technical notion of *style*.

Bally's concept of style is understood as the mark of a subjectivity expressed through the packaging of the informational content. His idea was that content can be conveyed according to various *modalities*. Well before Bakhtin's work became popular in pragmatics, Bally posited not only that an utterance bears the trace of viewpoints, but also that, generally speaking, utterances are echoing other utterances and mixing viewpoints from several real or imaginary speaking instances. This idea converged with notions further developed in pragmatics and discourse analysis such as polyphony and heterogeneity of discourse. His theoretical work goes hand-in-hand with a reflection on Saussurean notions such as *value* and *signification*, about which he developed original thoughts (in particular, he suggests a dichotomy between *actual* concept in *parole* and *virtual* concept in *langue* in a 1940 paper). Charles Bally was also concerned with the didactics of first language, and gave a series of lectures at the University of Geneva on that topic in 1930, where he adopts, as a follower of Saussure, a moderate anti-normative position and pleads for a more synchronic point of view (reprint Bally, 2004).

Albert Sechehaye's (1870–1946) main theoretical work, illustrated with French data, was to suggest a renewal of the theory of grammar by means of a constructive method, considering that complex syntactic forms can be reduced to basic syntactic forms (Sechehaye, 1926).

The other scholars of the Geneva School are Robert Godel, who focused on the edition of Saussurean archives and discussed, in light of them, key Saussurean concepts; Serge Karcevski, who exported the ideas of the Geneva School to the Moscow School; Henri Frei, who worked on Asian languages and on a theory of mistakes in communication (Frei, 1929); Luis Prieto, who, following a first move toward social psychology, understood semiology in relation with social practices (Prieto, 1975); André Burger, who studied romance languages; and René Amacker, who established close links with the Italian school of linguistics

and provided a treatise on Saussurean linguistics. The Geneva School has turned to discourse analysis with Eddy Roulet and is no longer directly connected with the works of Saussure and his followers. Nonetheless, research on the Saussurean heritage is still pursued in Geneva with publications including the periodical *Cahiers Ferdinand de Saussure* and the related series of volumes of the Ferdinand de Saussure Circle.

The Swiss scholar Rudolf Engler, who spent most of his career in Berne, is also associated with the Geneva School of linguistics. Although he wrote a valuable study on the arbitrariness of the sign, he is mostly well-known for his expert work and edition of Saussurean manuscripts. Having traced and examined the original sources available in the archives of Geneva, he established the classical synoptical edition of the *Cours* in the late 1960s. He died in 2003 after publishing newly found manuscripts with the French semiologist Simon Bouquet (Saussure, 2002).

It is worth noticing that the ideas developed in the Geneva School of linguistics were not grounded in the radical anti-realism developed in France and which later turned into the postmodern movement. Some French scholars radically interpreted Saussure's ideas on the rejection of reference (linguistic theory is not about reference) and assumed that there is no such thing as reference or objective knowledge. These ideas converged with increasingly popular ideas on radical anti-realism, nominalism, and solipsism supported by postmodern philosophers. Although Saussurean structuralism was understood by the Geneva scholars as founded on the relative and differential notion of *value*, they remained reluctant in adopting a radical view on these issues, probably because they were, as Saussure himself was, much concerned with empirical and descriptive adequacy.

Genre in Literary Studies

When, in the 18th century, English commentators wished to follow their classical predecessors, Plato and Aristotle, in distinguishing among types of artistic production, they borrowed the word *genre*, 'kind,' from French. The term was initially applied to literary texts, which had also been the concern of the classical commentators. All literary genres were considered to be recognizable by their adherence to conventions of form, content, and use of language. For example, Aristotle, in Chapter 6 of the *Poetics*, defined and described epic, lyrical, and dramatic poetry by identifying their constituent parts. Of tragic drama, he wrote (quoted in Dorsch, 1965: 39):

> Necessarily . . . every tragedy has six constituents, which will determine its quality. They are plot, character, diction, thought, spectacle, and song. Of these, two represent the media in which the action is represented, one involves the manner of representation, and three are connected with the objects of the representation; beyond them nothing further is required.

In a similar vein, but over 2000 years later, the Romantic essayist William Hazlitt began his *Lectures on the English Poets* (1818 [1910]: 1) by focusing on the content, form, and phonological features of poetry:

> In treating of poetry, I shall speak first of the subject-matter of it, next the forms of expression to which it gives birth, and afterwards of its connection with harmony and sound.

According to classical Greek literary theory, the distinction among lyric, epic, and dramatic poetry was found in their different use of narrative voice: In lyric poetry, only the narrator's voice was heard; in epic, the narrator spoke alongside the characters; and in dramatic poetry, only the characters' voices were heard. Despite a longstanding tendency among neoclassical commentators to treat genres as discrete and stable, writers inevitably mixed them; for instance, Shakespeare mixed prosaic comedy and tragic verse by following the murder of Duncan with the comic porter's scene in *Macbeth*, and in *Hamlet* (Act II, Scene ii), he parodied the critics of his time through Polonius's pedantic distinctions among the genres of 'tragedy, comedy, history, pastoral, pastoral-comical, historical-pastoral, tragical-historical, tragical-comical-historical-pastoral' and so on.

By Hazlitt's time, the proliferation of new genres, such as the novel, and the Romantic critic's preference for the unique and original over the generic and conventional led to the gradual decline of the importance of the concept of genre in literary studies. As a result, in literary studies and in other esthetic fields, such as art and film criticism, to describe something as a 'genre piece' was to stigmatize it, a process some writers and critics have been at pains to challenge (e.g., Braudy, 1985):

> No part of the film experience has been cited more consistently as a barrier to serious critical interest than the existence of forms and conventions, whether in such details as the stereotyped character, the familiar setting, and the happy ending, or in those films that share common characteristics – Westerns, musicals, detective films, horror films, escape films, spy films – in short, what have been called *genre* films. Genre films especially are criticized because they seem to appeal to a preexisting audience, whereas the film 'classic' creates its own special audience through the unique power of the film-making artist's personal creative sensibility.

In the 20th century, certain critics began to rehabilitate the concept of genre in literary studies. Rather than conceiving of genre as a fixed, absolute set of conventions, however, modern critics see genre as a dynamic set of conventions that are related to changing social institutions and purposes. Structuralist critics redefine genre as a set of expectations that a reader acquires from his or her reading. These expectations may be fulfilled or frustrated in any further act of reading, each one of which reshapes one's generic expectations. The literary critic's role, therefore, is not to state the formulas to which literary texts must adhere, but, at least in part, to expose the expectations that account for particular esthetic responses. The structuralist critic also tends to favor those works of literature that set out to challenge prevailing expectations through parody or denial, as Eichenbaum (1925; cited in Scholes, 1974: 88) noted:

> In the evolution of each genre there are times when its use for entirely serious or elevated objectives degenerates and produces a comic or parodic form. The same phenomenon has happened to the epic poem, the adventure novel, the biographical novel, etc.

Eichenbaum argued that the genre is 'regenerated' through the playful subversion of conventions that enable the creation of new forms.

Genre in Language Studies

Structuralist critics view literature as a self-contained system with its own codes and conventions. In contrast, another major figure, Mikhail Bakhtin, related literary language to the wider and hitherto neglected

system of codes and expectations governing discourse in general. In 'The Problem of Speech Genres,' Bakhtin (1952–1953 [1986]: 60) wrote:

> Each separate utterance is individual, of course, but each sphere in which language is used develops its own *relatively stable types* of these utterances. These we may call *speech genres* . . . Special emphasis should be put on the extreme *heterogeneity* of speech genres (oral and written). In fact, the category of speech genres should include short rejoinders of daily dialogue (and these are extremely varied depending on the subject matter, situation, and participants), everyday narration, writing (in all its various forms), the brief standard military command, the elaborate and detailed order, the fairly variegated repertoire of business documents (for the most part standard), and the diverse world of commentary (in the broad sense of the word: social, political). [italics in original].

In language studies, in the decades following Bakhtin, the term 'genre' has been appropriated by linguists who wish to explore nonliterary spoken and written discourse in which expectations of conventional use of text structure, lexis, and syntax are likely to be satisfied; for example, academic research articles, letters of application for employment, recipes, and so-called 'service encounters' in which customers interact with shopkeepers in order to purchase goods. Despite common interests, there is considerable divergence in why and how these linguists use the term 'genre' and undertake genre analysis.

Genre in Systemic-Functional Linguistics

Systemic-functional linguists employ genre as part of their project to relate language use to its social context, in particular, 'the context of culture.' Interest in genre arose out of a growing sense of the inadequacy of the concept of 'register' to account for the contextual aspects of text. Register analysis assumes that textual features can be predicted because texts vary conventionally in relation to three 'situational variables'; namely, 'field' (subject matter), 'tenor' (relationship between participants in the interaction), and 'mode' (whether the text is written or spoken). These situational variables did not deal with *why* the text might have been written or spoken. The realization that a text might be shaped and so categorized in relation to its communicative purpose led to a resurgence of interest in a text's genre; that is, how a text relates systematically to its context of culture.

For example, the register of entries in travel guidebooks might vary according to the writer's relationship with the intended readership (a formal relationship with erudite connoisseurs of, say, art history and architecture, or an informal relationship with student backpackers); the subject matter covered by the entries (fields such as food, wine, history, architecture, beaches, night clubs, and various types of accommodation); and the mode (usually written but possibly with some appeal to spoken discourse in the less formal realizations). None of these situational variables takes into consideration *why* tourist guidebooks come to be written; in other words, their context of culture. Analysis of the genre of travel guidebooks would consider the cultural phenomenon of tourism: the fact that different types of people choose to travel as a leisure pursuit in which they gaze at certain things (landscape, certain buildings), eat certain kinds of food, and indulge in particular leisure pursuits (swimming, clubbing, visiting galleries, shopping for souvenirs) before moving on. A consideration of the genre of a text helps account for its content, as well as its form: A generic text is one in which conventional characteristics have developed out of an evolving set of cultural imperatives.

Systemic-functional linguists begin to analyze the genre of a text by assuming that its overall purpose is met through a sequence of stages, each of which achieves an intermediate purpose. The analyst seeks, through observation of a number of related communicative events, first to identify these stages and then to decide which are optional and which are obligatory, as well as their possible chronological order. Ideally, the analyst then arrives at the "generic structure potential" (Halliday and Hasan, 1989: 63–69) of a set of communicative events. Hasan recorded a number of 'service encounters' at a grocery, which yielded several apparently obligatory elements that she termed sale request, sale compliance, sale purchase, and purchase closure. These obligatory moves were sometimes combined with several optional elements. Hasan's notion of generic structure potential involved a considerable level of detail. The elements were not only shown to be compulsory or optional but they were also put in predictable sequences and recursive elements were identified.

Though fewer of her successors dared to be quite so detailed in their formulation of generic structure potential, Hasan's work was followed, for example, by Ventola's (1987) crosscultural comparison of Finnish and Australian English talk in a post office and gift shop and by McCarthy's (2000) discussion of talk in a hairdresser's salon and during driving lessons. McCarthy's study was particularly concerned with the interplay between the relatively predictable 'transactional talk' (which, in a hairdresser's salon, included 'arrival and checking in for appointment.' 'discussion of how the client's hair is to be cut,' and 'payment/closure at desk') and the less predictable 'interactional talk,' such as evaluative comments on the smell of the shampoo, the shape of the protective

gown, or casual conversation about the hairdresser's life and recent experiences. McCarthy argued that, though it is less predictable, the interactional talk is as important as the transactional, because it is the former type of talk that manages the client–customer relationship.

Unpredictability is an issue for genre analysis, and it is fair to say that much genre analysis favors conventional situations. Kress (1985: 19) went so far as to argue that most situations are conventional and, therefore, produce texts that can be characterized as 'generic':

> The social occasions of which texts are a part have a fundamentally important effect on texts. The characteristic features and structures of those situations, the purposes of the participants, the goals of the participants all have their effects on the form of the texts which are constructed in those situations. The situations are always conventional. That is, the occasions on which we interact, the social relations which we contract, are conventionalized and structured, more or less thoroughly, depending on the kind of situation it is. They range from entirely formulaic and ritualized occasions, such as royal weddings, sporting encounters, committee meetings, to family rituals such as breakfast or barbecues or fights over who is to do the dishes. Other, probably fewer occasions are less ritualized, less formulaic; casual conversations may be an example.

Despite Kress's skepticism about casual conversation, McCarthy's (2000) discussion of interactional talk and Eggins and Slade's (1997) exploration of casual conversation suggested that casual talk is at least partly amenable to genre analysis. Eggins and Slade (1997: 229) identified, for example, different types of narrative that populate everyday talk, and they proposed a generic structure for gossip. They made the following observation:

> Storytelling is very common in casual conversation. It provides conversationalists with a resource for assessing and confirming affiliations with others.

Like McCarthy, Eggins and Slade viewed interactional speech genres as crucial in establishing, negotiating, and maintaining group identity. Through stories that illustrate and dramatize cultural values, conversational participants manage in-group membership.

Ultimately, what distinguishes the systemic-functional genre analyst is his or her focus on the text (spoken or written) as the source of evidence for generic classifications. The procedure is an iterative one: The analyst gathers together examples of the genre, looks at their structure, and breaks each example down into purpose-driven stages. Because each stage has a different purpose, the assumption is that each stage will be differently realized linguistically. The analyst, therefore, seeks to describe the 'realization patterns' of each stage of the generic text. The presence of distinctive patterns reinforces or challenges the analyst's intuition that the texts are generically related. Critics argue that the procedure is circular: If the analyst finds an example that does challenge his or her intuition, the model is simply adapted to accommodate the awkward text. Thus, the model is never 'proven wrong.' However, advocates of this type of genre analysis would counter that the circularity of the process is inevitable; describing the potential structure of a genre entails an ongoing series of refinements, because the nature of a genre changes as society's demands evolve (e.g., Halliday and Martin, 1993). The way that society shapes genres is the focus of the approach taken by North American school of analysts known as the 'New Rhetoricians.'

Genre in 'the New Rhetoric'

The evolving nature of genres is a preoccupation for at least some of the American genre analysts known as the 'New Rhetoricians' (cf., Freedman and Medway, 1994). The focus of the New Rhetoric is "centered not on the substance or the form of discourse but on the action it is used to accomplish" (Miller, 1984: 151). This school of genre analysts, therefore, situates genres in a thick ethnographic description of the communities that give rise to them, whether these communities are tax accounting firms (Devitt, 1991), bank offices (Smart, 1993), or scientific researchers (Bazerman, 1988; Myers, 1990).

For example, Bazerman (1988) looked at the gradual evolution of the experimental article in science and accounted for its changing form and structure in the evolving character and activities of the academic communities that have increasingly come to communicate through research papers. Thus, the experimental article grew out of the broadening of the scientific community in the age of Newton and of the substitution of the replicable experiment for the public demonstration. As experiments became more sophisticated and costly, replicability in principle replaced replication in practice; meanwhile, the success of the physical sciences gave their preferred forms of communication a prestige that was borrowed by other disciplines such as psychology and the social sciences. In those disciplines that are less obviously amenable to empirical research, the formal elements of the research article have a persuasive as much as a practical function. The moral of the New Rhetoricians' work on genre is that it is a negotiable 'social fact,' rather

than an invariable set of conventions, as for example, in Bazerman (1988: 8):

> Formal definitions, expected features, institutional force, impact, and understandings of the genre vary through time, place, and situation. That variation is an important part of the story. Each new text produced within a genre reinforces or remolds some aspect of the genre; each reading of a text reshapes the social understanding. The genre does not exist apart from its history, and that history continues with each new text invoking the genre.

Although New Rhetoricians are concerned that students understand the history and changing nature of genres, they are less inclined to offer formulaic descriptors of specific generic texts. In this, they differ both from the systemic functionalists and from those who come to genre analysis from applied linguistics, and specifically English for Specific Purposes (ESP).

Genre in Applied Linguistics

Applied linguists' analyses of genre share something of the approaches of both the systemic-functionalist school and the New Rhetoricians. Like the latter, they favor ethnographic descriptions of the 'discourse communities' who use genres to achieve social actions (cf., the notion of a 'rhetorical community' proposed by Miller, 1994). It is the needs of the discourse communities that are linked to the formal qualities of generic texts, usually described as a sequence of 'moves' that recall the generic structure potential of the systemic functionalists.

One of the best-known accounts of genre in this tradition is Swales' (1981, 1990) account of research article introductions in the sciences and social sciences. He refined his model into a three-move sequence, the overall function of which within the academic community is to 'create a research space.' This goal is accomplished by 'establishing a territory' (for example, by making a topic generalization and surveying the literature); 'establishing a niche' (for example, by questioning past research or adding to its scope); and 'occupying the niche' (for example, by previewing one's own research). Within the research community, the research article introduction is used rhetorically to align oneself with or against a research tradition and to frame stronger and weaker claims to knowledge. Further work along these lines has been published on business correspondence (Bhatia, 1993), quantity surveying reports (Marshall, 1987), and economics discourse (Dudley-Evans and Henderson, 1990).

Where systemic functionalists rely initially on the genre analyst's intuitions to break down a text into purposive stages, focusing mainly on multiple examples of the text type and looking for realizational patterns that justify the intuitive categorizations, the applied linguist checks his or her stages or moves against evidence garnered from the discourse community, through observation and interview.

Changing Conceptions of the Discourse Community

The 'discourse community' concept was based on the sociolinguistic notion of the speech community, whereby similarities in speech could be accounted for by the speakers' living in a community defined by geographical space, social class, gender, ethnicity, and so on. In a discourse community, the members may be dispersed widely and of different social classes, genders, and ethnicities, but they are linked by a common set of communicative purposes; for example, they might need to write research articles for international refereed journals, or they might need to write business letters, such as letters of application for a job. For Swales (1990), discourse communities have six identifying characteristics:

1. A discourse community has a broadly agreed set of common public goals.
2. A discourse community has mechanisms of intercommunication among its members.
3. A discourse community uses its participatory mechanisms primarily to provide information and feedback.
4. A discourse community uses and hence possesses one or more genres in the communicative furtherance of its aims.
5. In addition to owning genres, a discourse community has acquired some specific lexis.
6. A discourse community has a threshold level of members with a suitable degree of relevant content and discoursal expertise.

The influence on Swales' work of academic genres is clearly discernible here. A group of physicists or biologists, say, would have a set of research goals, journals, and conferences with which to give information and feedback. The group would have several genres at its disposal (research articles, reports to funding agencies, conference papers, popularizations), and its members would have relevant expertise (they would all likely be educated to degree level and beyond). However, more recent work has addressed the restrictive and static nature of this tentative description of the discourse community. It is difficult to fit diffuse discourse communities into Swales's model: What is the discourse community that produces and reads, say, a tabloid newspaper, or even a popular science article in a magazine like *New Scientist?* In those examples, writers and readers

seem to have different levels of expertise. Junk mail seems to be a genre, but it is difficult to characterize the discourse community that produces or consumes it. Several attempts have been made to redefine the discourse community. Consider Barton's (1994: 57) definition:

> A discourse community is a group of people who have texts and practices in common, whether it is a group of academics or the readers of teenage magazines. In fact, discourse community can refer to several overlapping groups of people: It can refer to the people a text is aimed at; it can be the people who read a text; or it can refer to the people who participate in a set of discourse practices both by reading and writing.
